

# Singularities driven turbulence

**Christophe Josserand**, Yves Pomeau and Sergio Rica  
LadHyX, CNRS & Ecole Polytechnique, IP Paris

# Motivation-context

- Role (and in fact existence) of singularities (or at least extreme events) in turbulence
- Singularities in Navier-Stokes equations (back to Leray 1934) are still a question of debates
- Extreme events (vorticity collapses) have been predicted and observed numerically (Siggia-Pumir 1987, Brachet et al 1992 for instance) and experimentally (Meneveau-Sreenivasan 1987). They are expected to be responsible of the intermittence in turbulence
- Difficult to handle in fluid flows: can we investigate a simpler model where we know the singularities (hard turbulence 89-90, burgulence Bec-Frisch 2000')?

# Intermittent fluctuations of the energy dissipation (Meneveau & Sreenivasan, Nuclear Physics B, 1987)

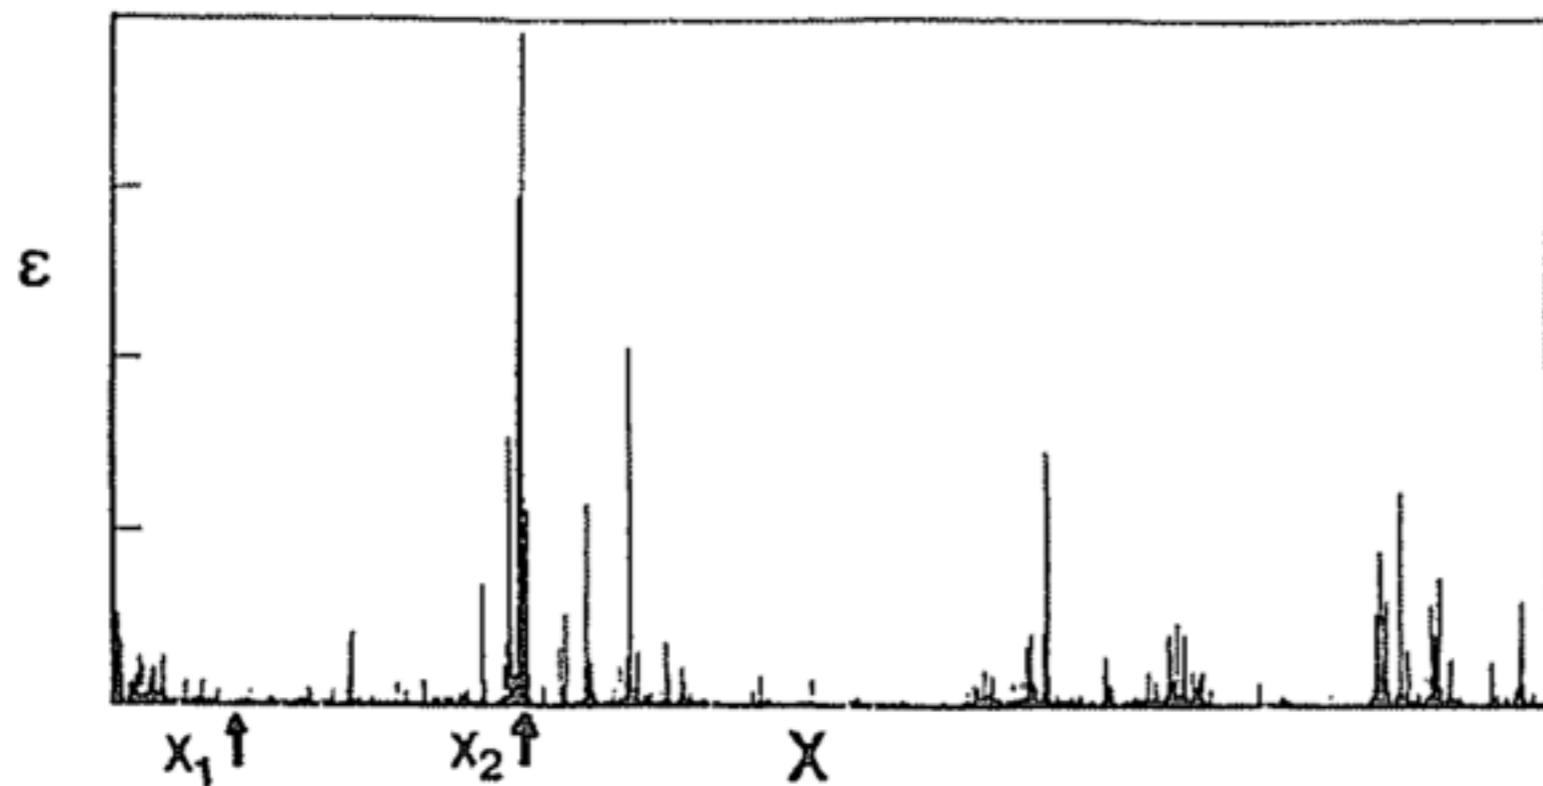

Figure 1a. Typical time trace of  $(\partial u_1 / \partial t)^2$ , representative of the rate of dissipation of turbulent kinetic energy.

# Focusing NLS

$$i\frac{\partial \psi}{\partial t} = -\frac{\alpha}{2}\nabla^2\psi - g|\psi|^{2n}\psi$$

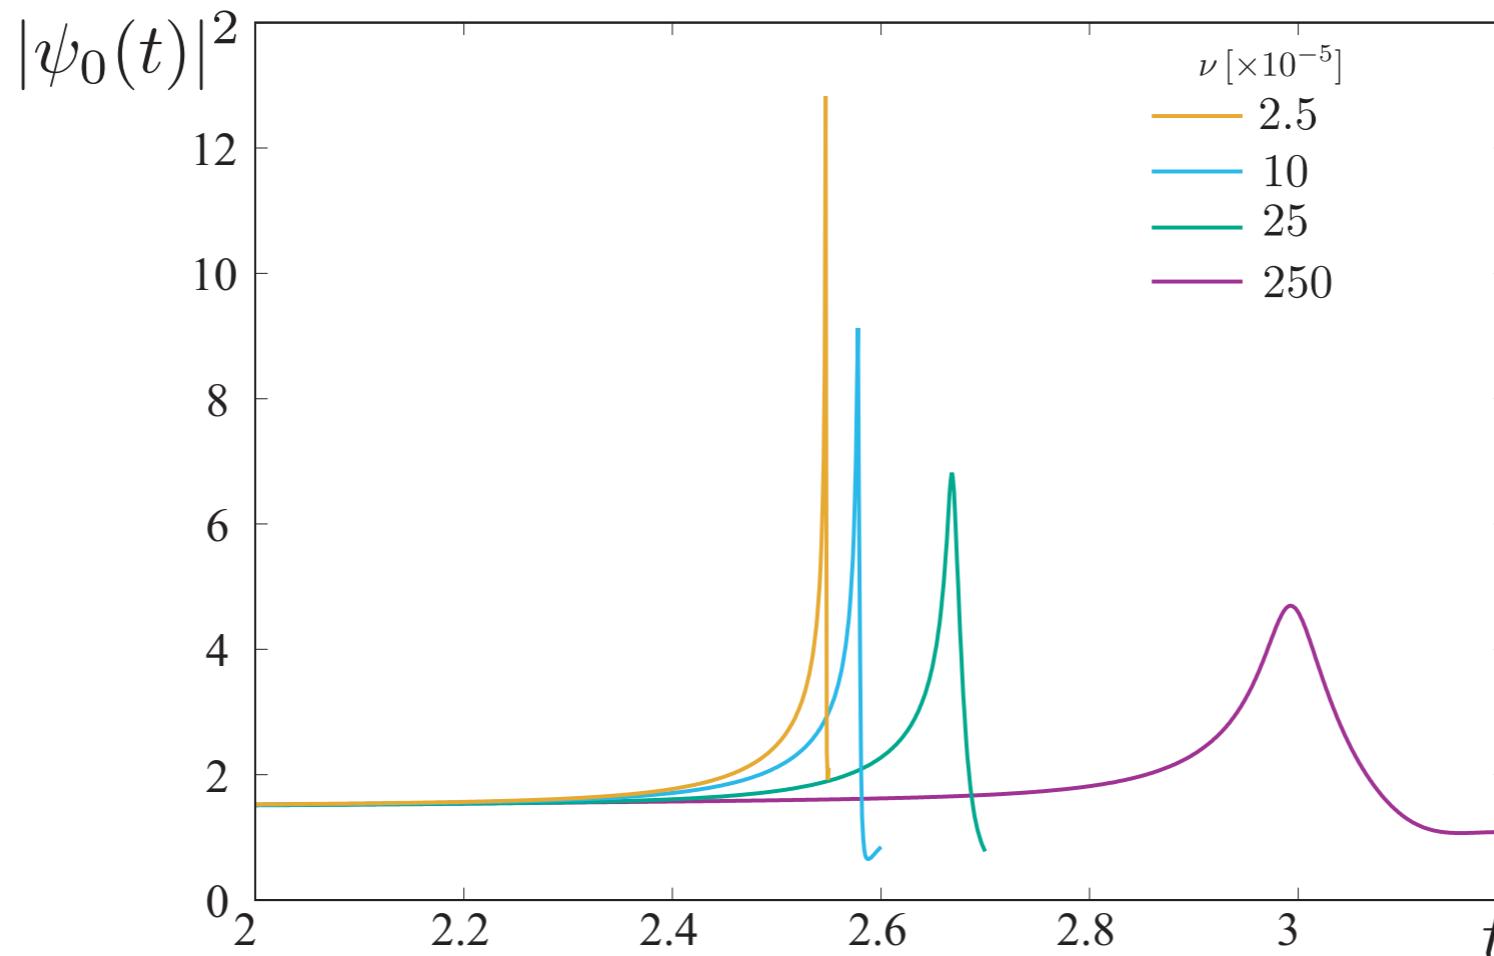

- $\psi(\mathbf{x}, t)$  is a complex field
- the NLS equation is a model for BEC, shallow-water and nonlinear optics.
- Hamiltonian structure and mass conservation

$$N = \int |\psi|^2 d\mathbf{x}$$

$$H = \int \left( \frac{\alpha}{2} |\nabla \psi|^2 - \frac{g}{n+1} |\psi|^{2(n+1)} \right) d\mathbf{x}$$

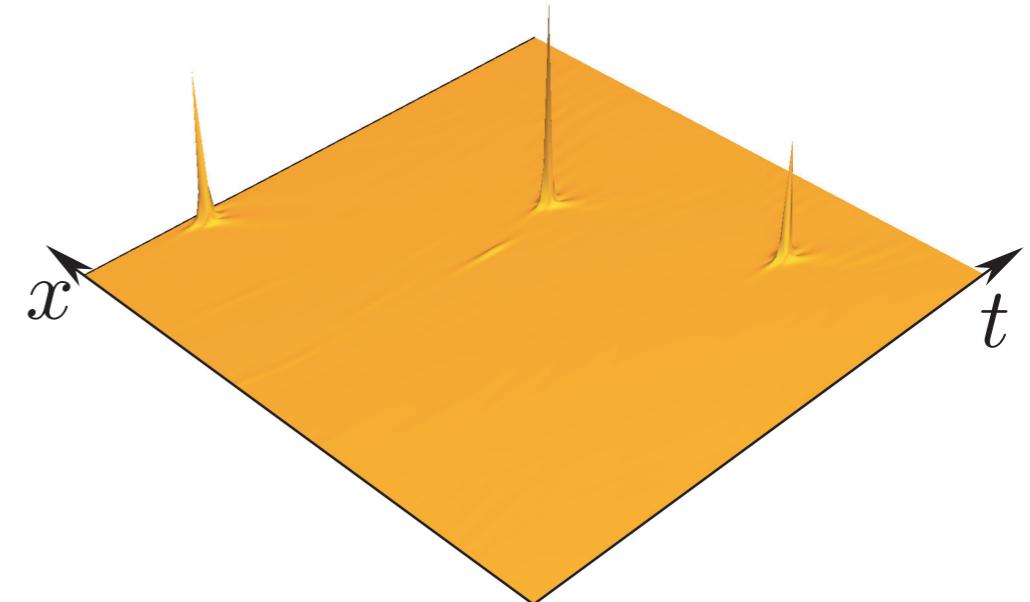

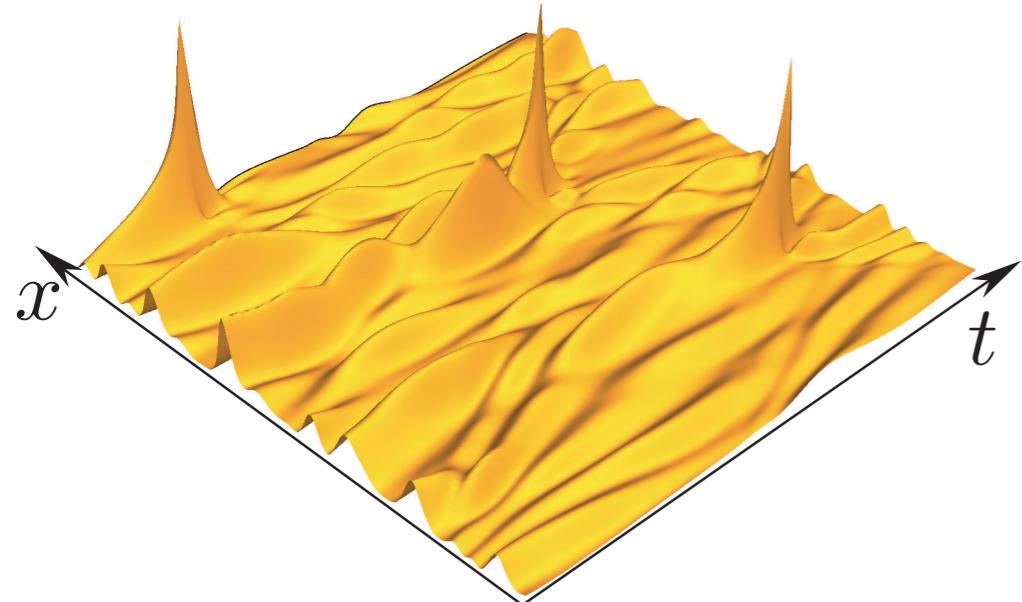

# Singularity in NLS

- for the focusing NLS ( $g=1$ ), the dynamics exhibits finite time and space singularities for  $nd>2$  (see for instance Le Mesurier et al 1988)
- The singularity is due to the non positive defined Hamiltonian
- this finite time singularity is suppressed in the presence of dissipation

$$i\frac{\partial \psi}{\partial t} = -\frac{\alpha}{2}\nabla^2\psi - g|\psi|^{2n}\psi - i\nu\Delta^2\psi + f_{k_0}(\mathbf{x}, t).$$

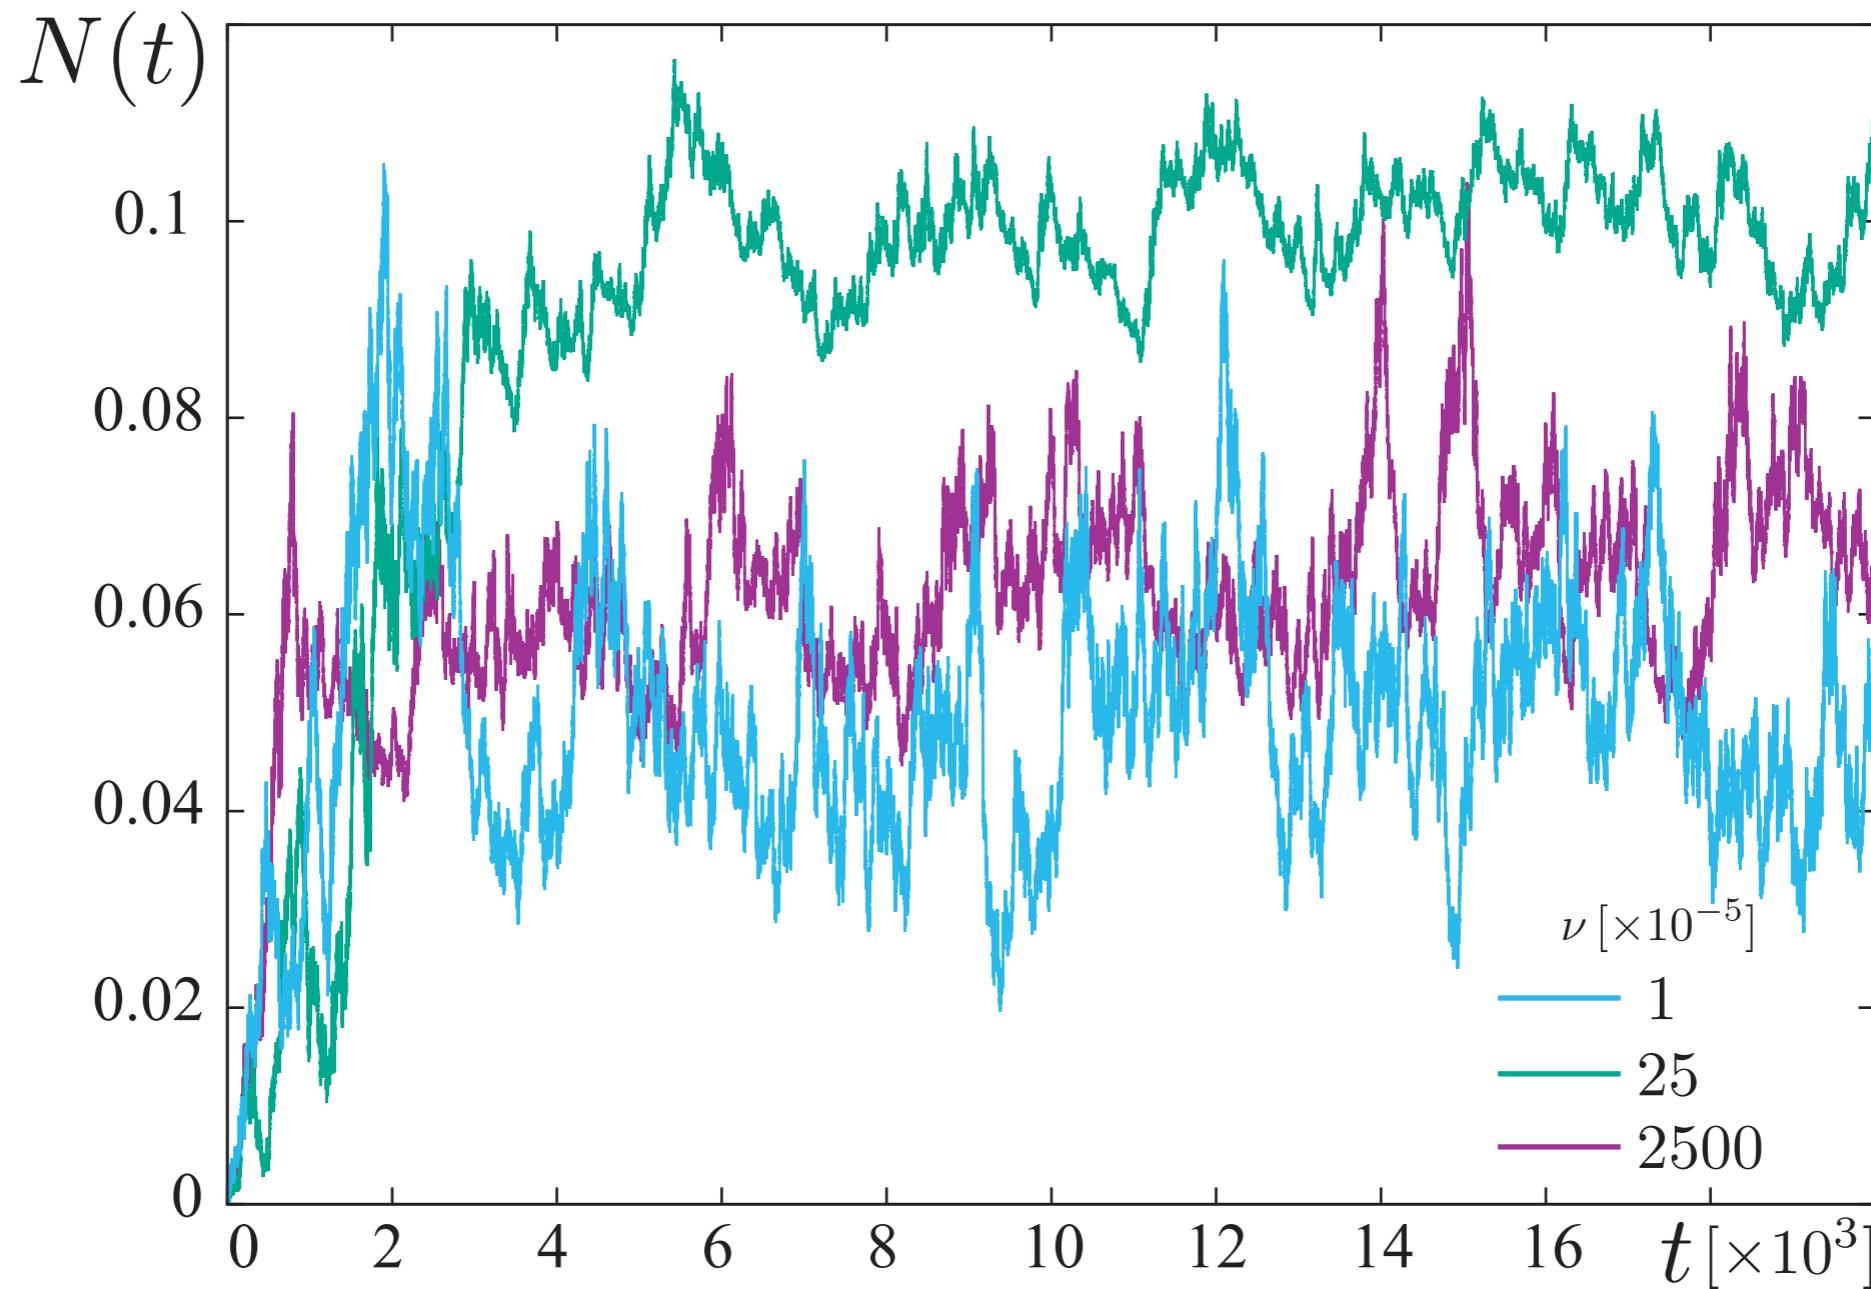

- with injection at large scale: turbulence of singularity or collapses (Dyachenko et al 1992, M. Bartuccelli et al 1989 & 1990)
- important difference: here the mass (positive definite) is the pertinent quantity for investigating turbulence
- wave turbulence (often observed in NLS equations) would suggest *inverse* cascade of mass and direct of energy
- focus here on the 1D case with n=3 (work in progress in 2 and 3D)
- numerical simulations

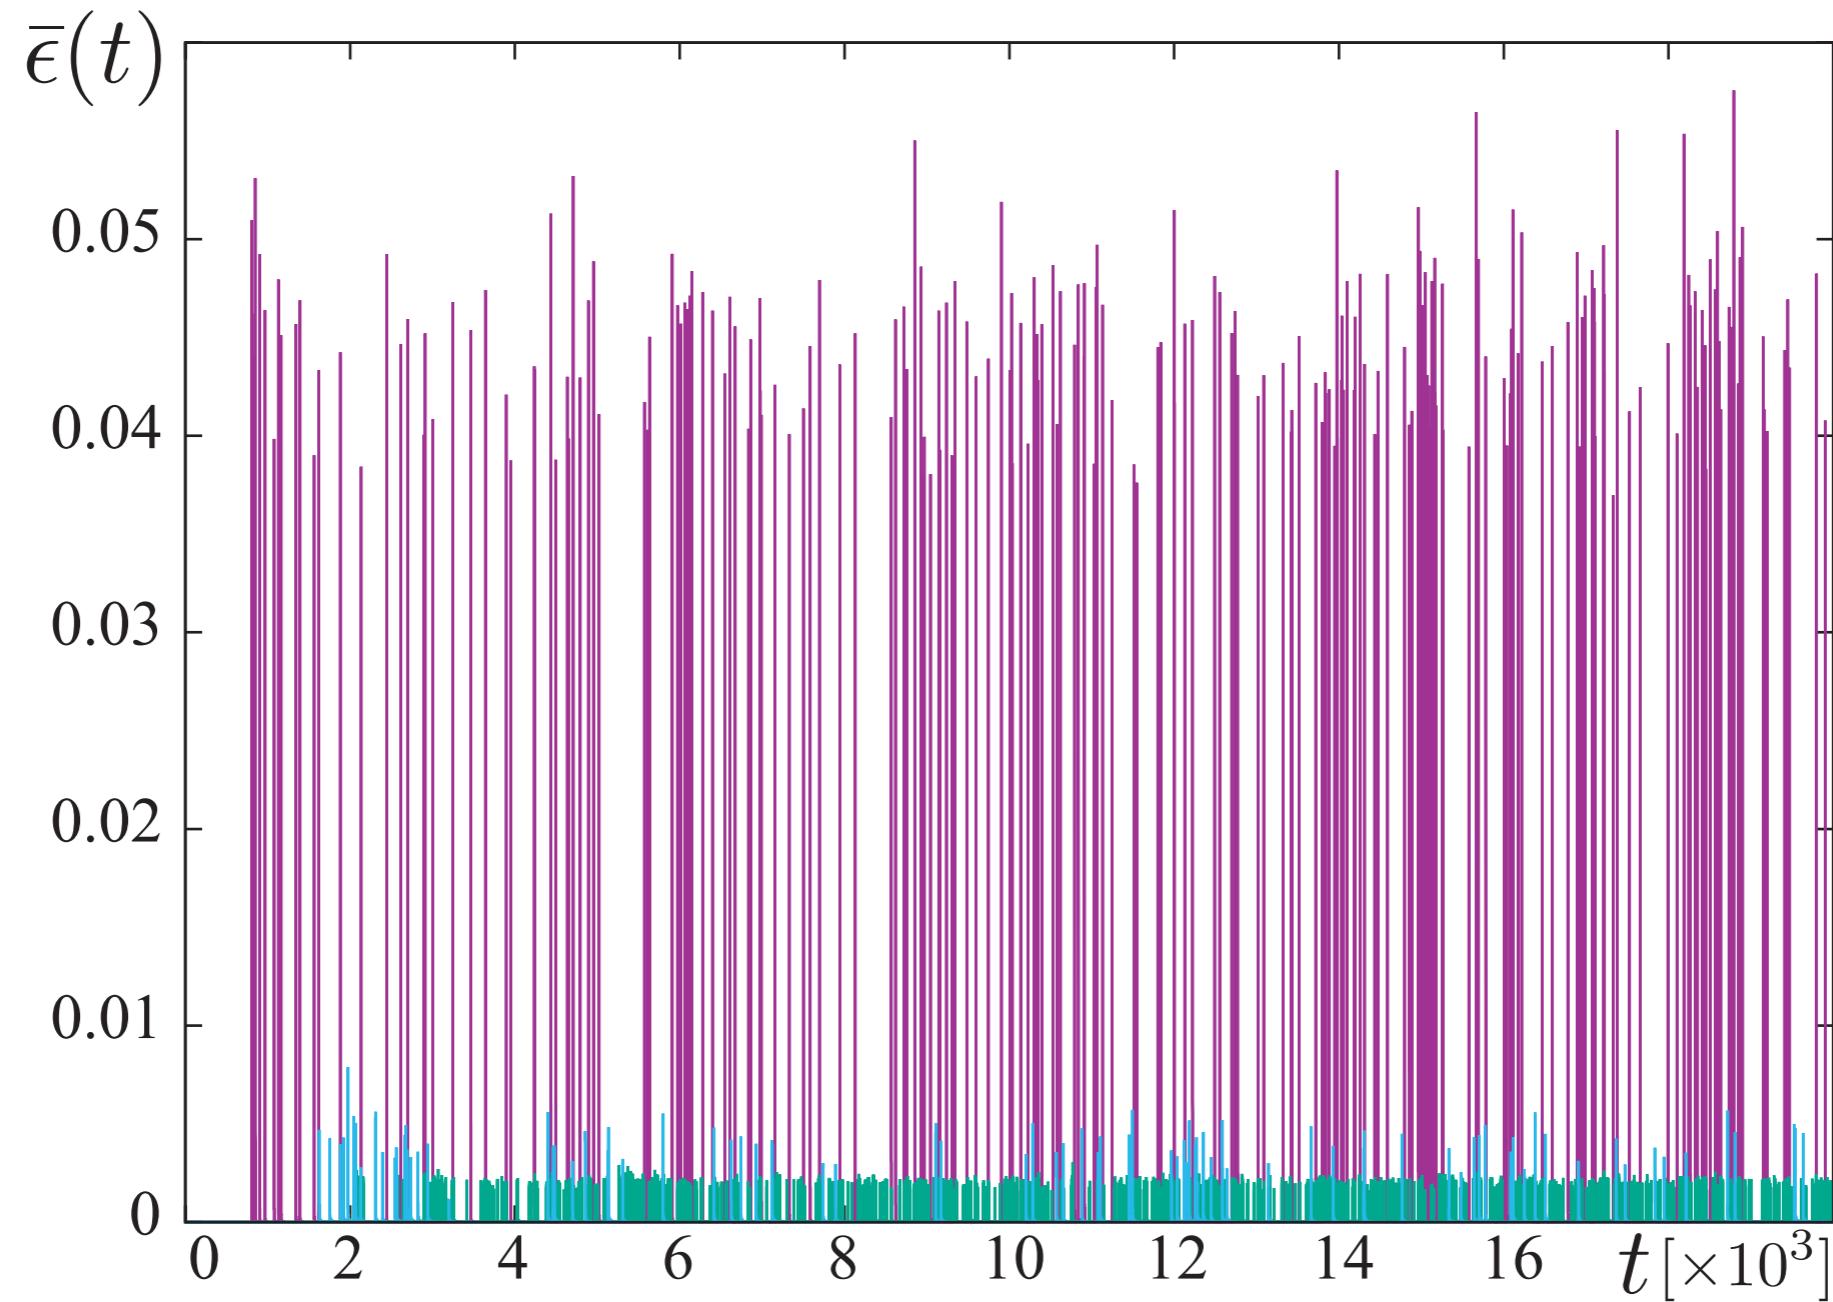

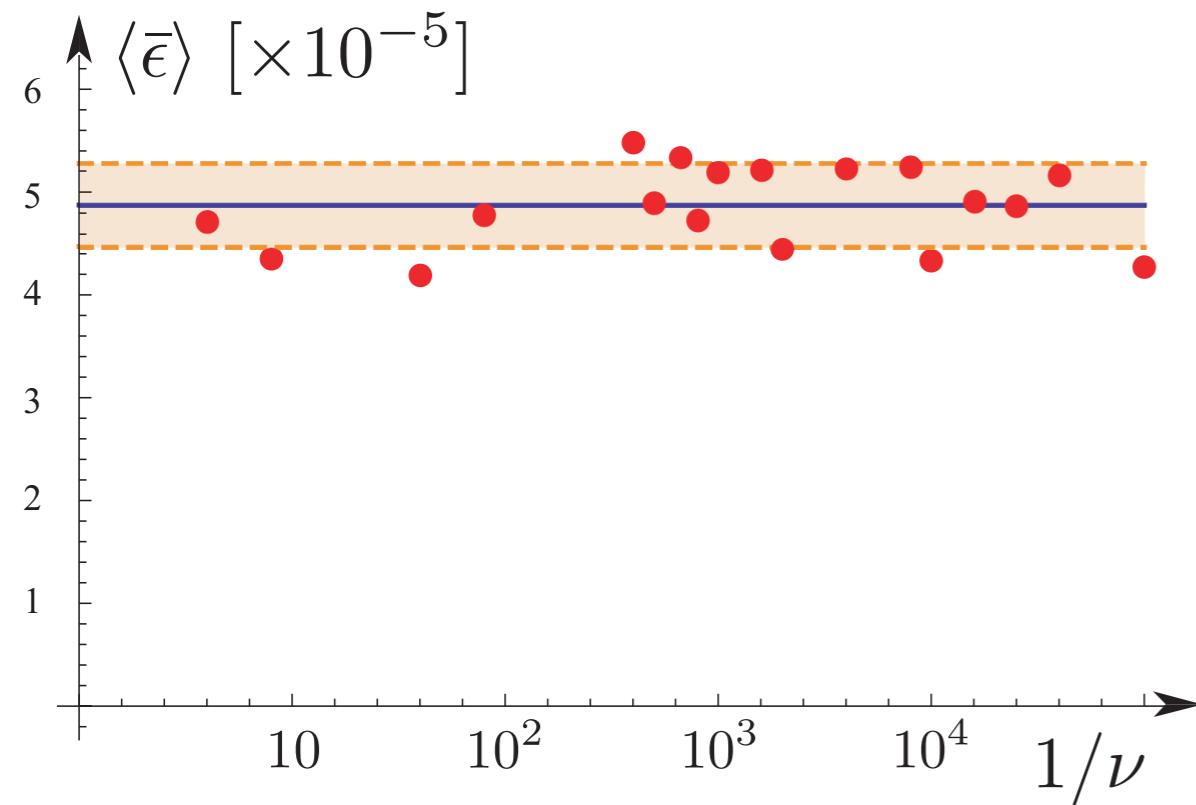

- « singularity » collapse or peak is followed by wave emission
- « dissipation » of mass is concentrated at short scale on the peaks:

$$\frac{dN}{dt} = -2\nu \int |\Delta\psi|^2 d^D\mathbf{x} + i \int (\psi \bar{f}_{k_0} - \bar{\psi} f_{k_0}) d^D\mathbf{x}.$$

# Varying only the viscosity

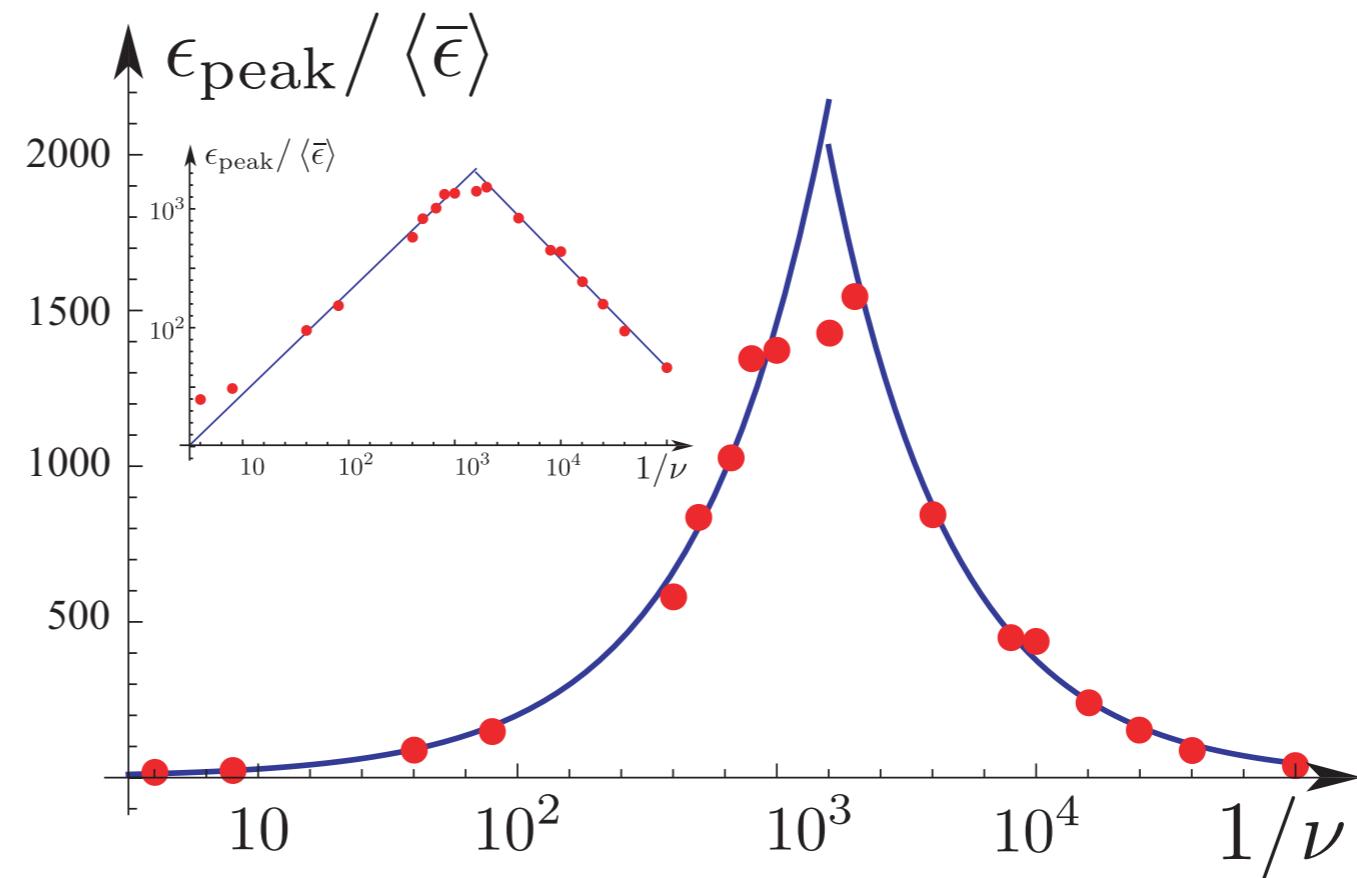

Anomalous  
dissipation?

Warning:

$$\nu \times |\Delta\psi|^2$$

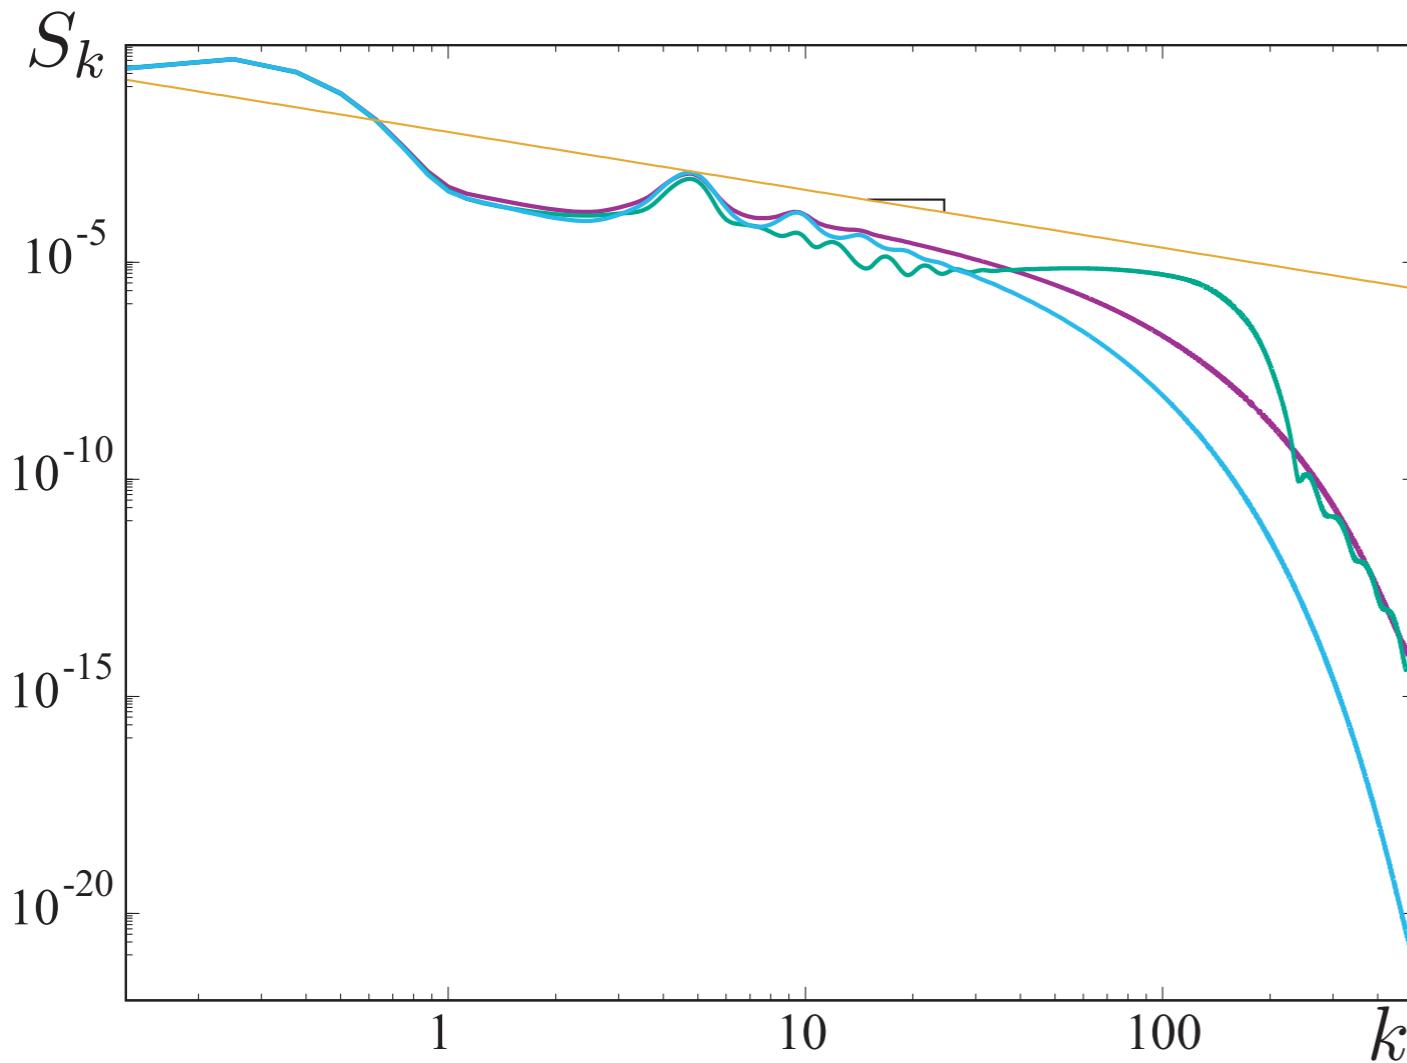

# Spectrum

$$S_k(t) \equiv |\hat{\psi}_k|^2 + |\hat{\psi}_{-k}|^2$$

$$\frac{1}{L} \int |\psi|^2 d\mathbf{x} = \int |\hat{\psi}_k|^2 d\mathbf{k}$$

- Spectrum fluctuates at collapse

$$\frac{1}{t} \sim \frac{1}{x^2} \sim |\psi|^6$$

$$|\psi|^2 \sim x^{-2/3}$$

$$|\psi_k|^2 \sim k^{-4/3}$$

- spectrum of the self similar collapse

$$S_k \propto k^{-4/3}$$

- Transport equation for the spectrum

$$\frac{\partial S_k}{\partial t} = -\frac{\partial Q_k}{\partial k} - 2\nu k^4 S_k + F_k$$

- Need to consider averaged in time spectra for which we have

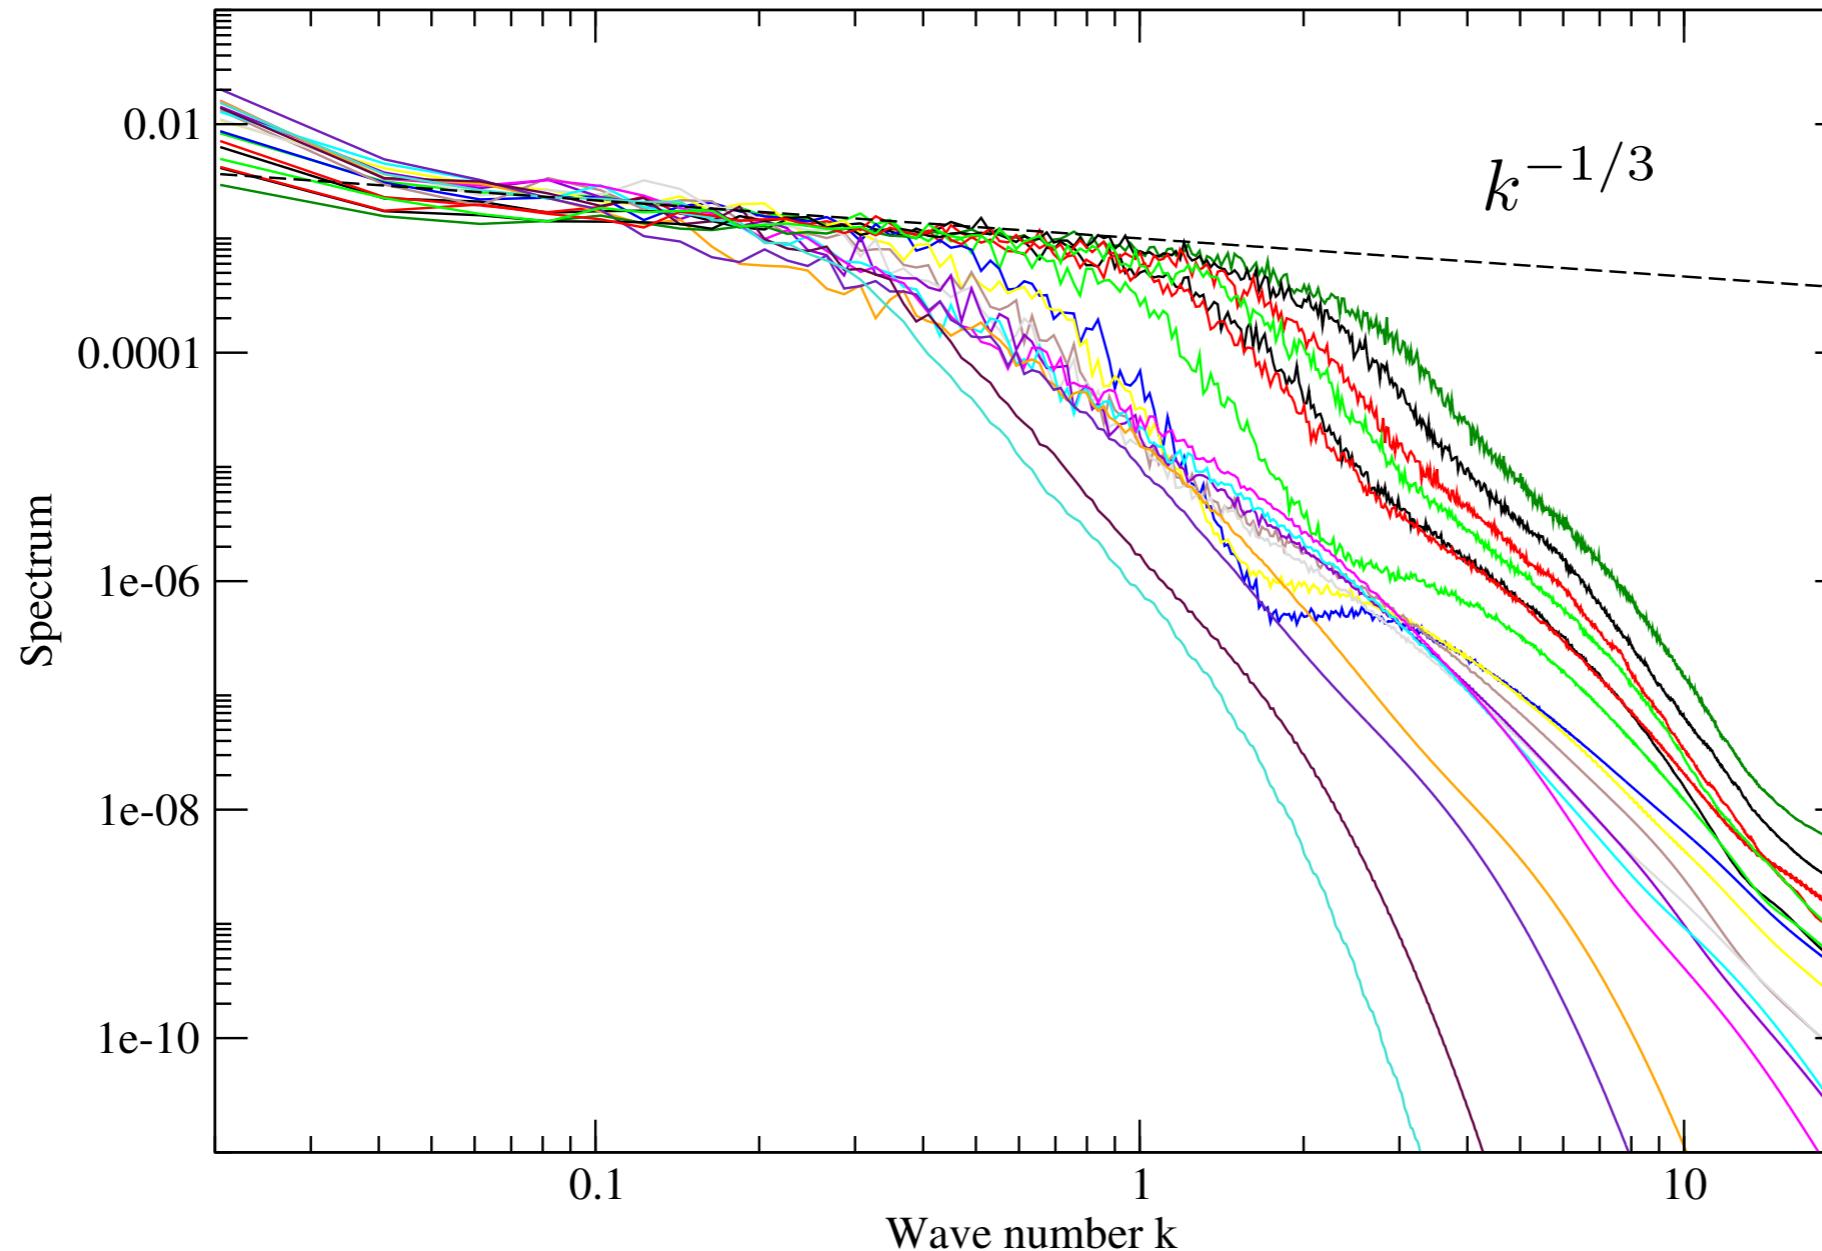

$$\frac{\langle \partial S_k \rangle}{\partial t} = 0$$

- In the inertial range we obtain also

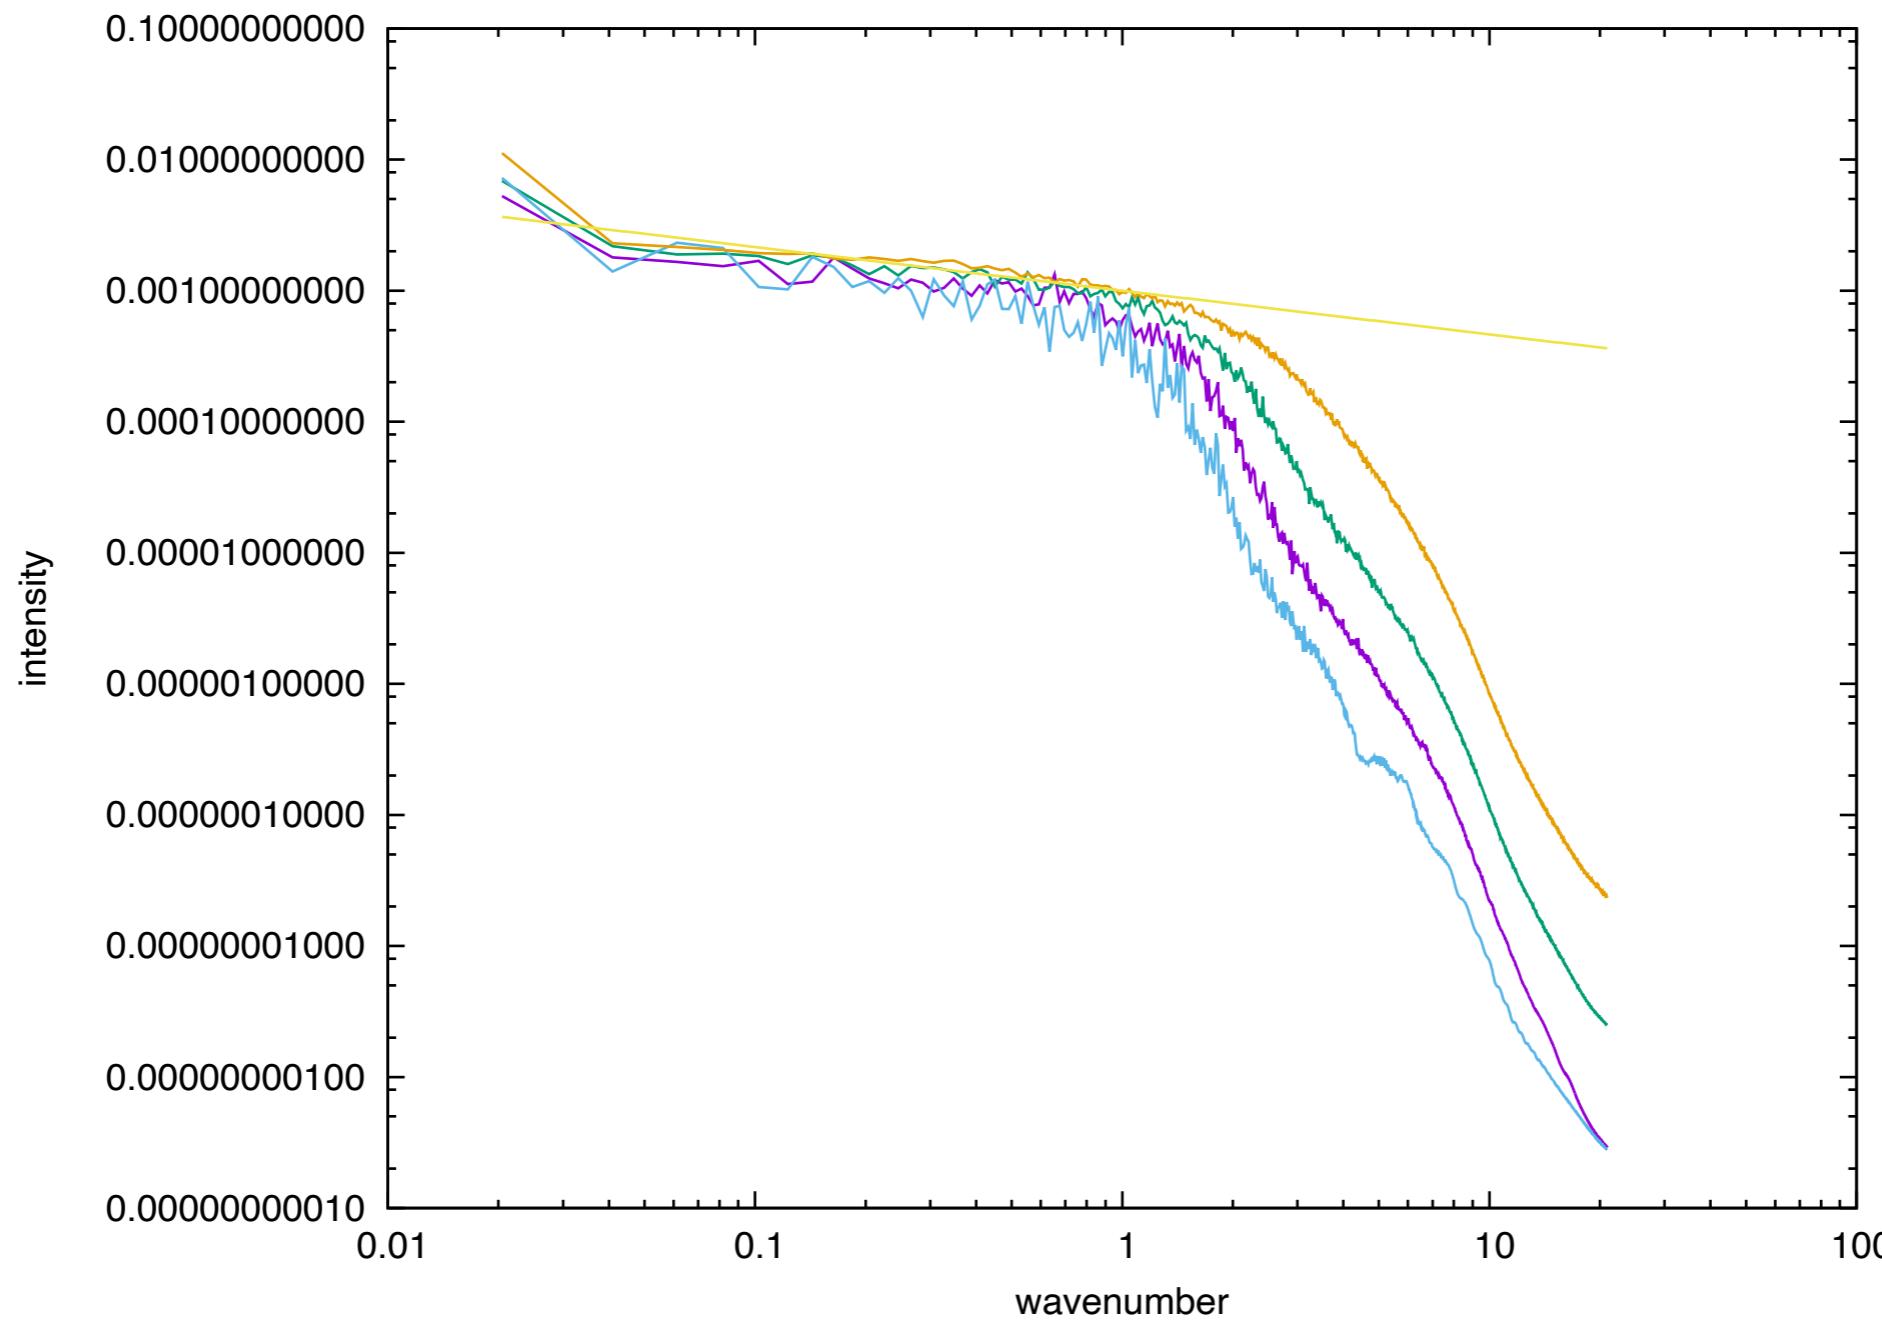

$$\langle Q_k \rangle = -2\nu \int_k^\infty k^4 \langle S_k \rangle dk \equiv \langle \epsilon \rangle$$

-

Spectrum expands in  $k$  as the viscosity decreases. Its amplitude seems independent of the injection rate

# Varying the injection

Phillips spectrum?

# Kolmogorov-like scaling analysis

$$[S_k] = \rho\ell \quad [\epsilon] = \rho\tau^{-1} \quad [\alpha] = \ell^2\tau^{-1} \quad [g] = \rho^{-3}\tau^{-1}$$

$$\langle S_k \rangle = \frac{\langle \bar{\epsilon} \rangle}{\alpha k^3} F \left( \frac{\alpha k^2}{(g \langle \epsilon \rangle^3)^{1/4}} \right)$$

If we look for a solution independent of the injection rate

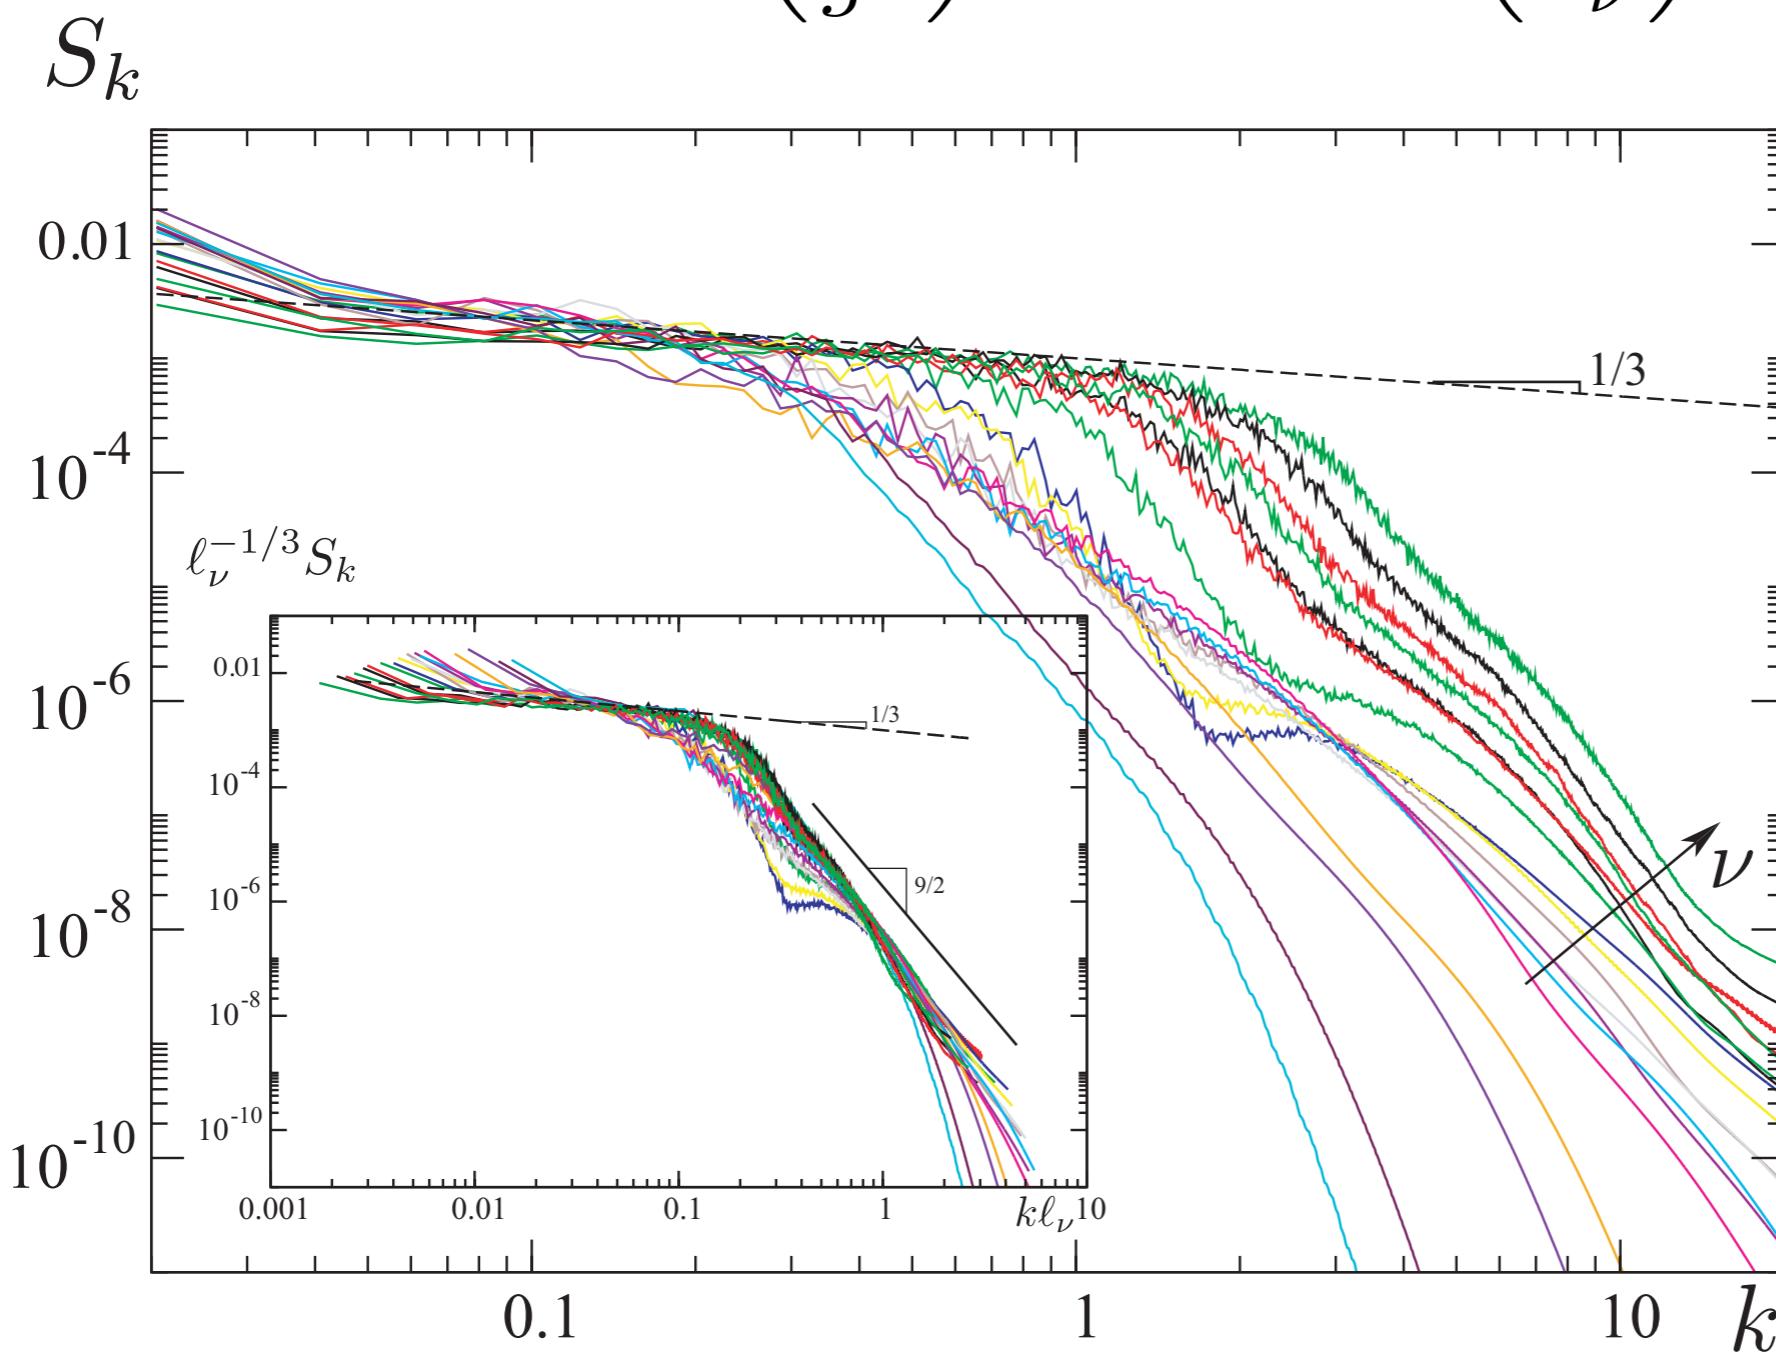

$$\langle S_k \rangle \propto \left( \frac{\alpha}{g^4} \right)^{1/3} k^{-1/3}$$

Kolmogorov scale  $\ell_\nu \sim \left( \frac{\alpha \nu^3}{g \bar{\epsilon}^3} \right)^{1/14}$

$k_\nu \sim \left( \frac{g \bar{\epsilon}^3}{\alpha \nu^3} \right)^{1/14}$

Suggest the following self-similar scaling for the spectrum

$$\langle S_k \rangle = \left( \frac{\alpha}{g^4} \right)^{1/3} k_\nu^{-1/3} G \left( \frac{k}{k_\nu} \right)$$

# Intermittency-structure functions

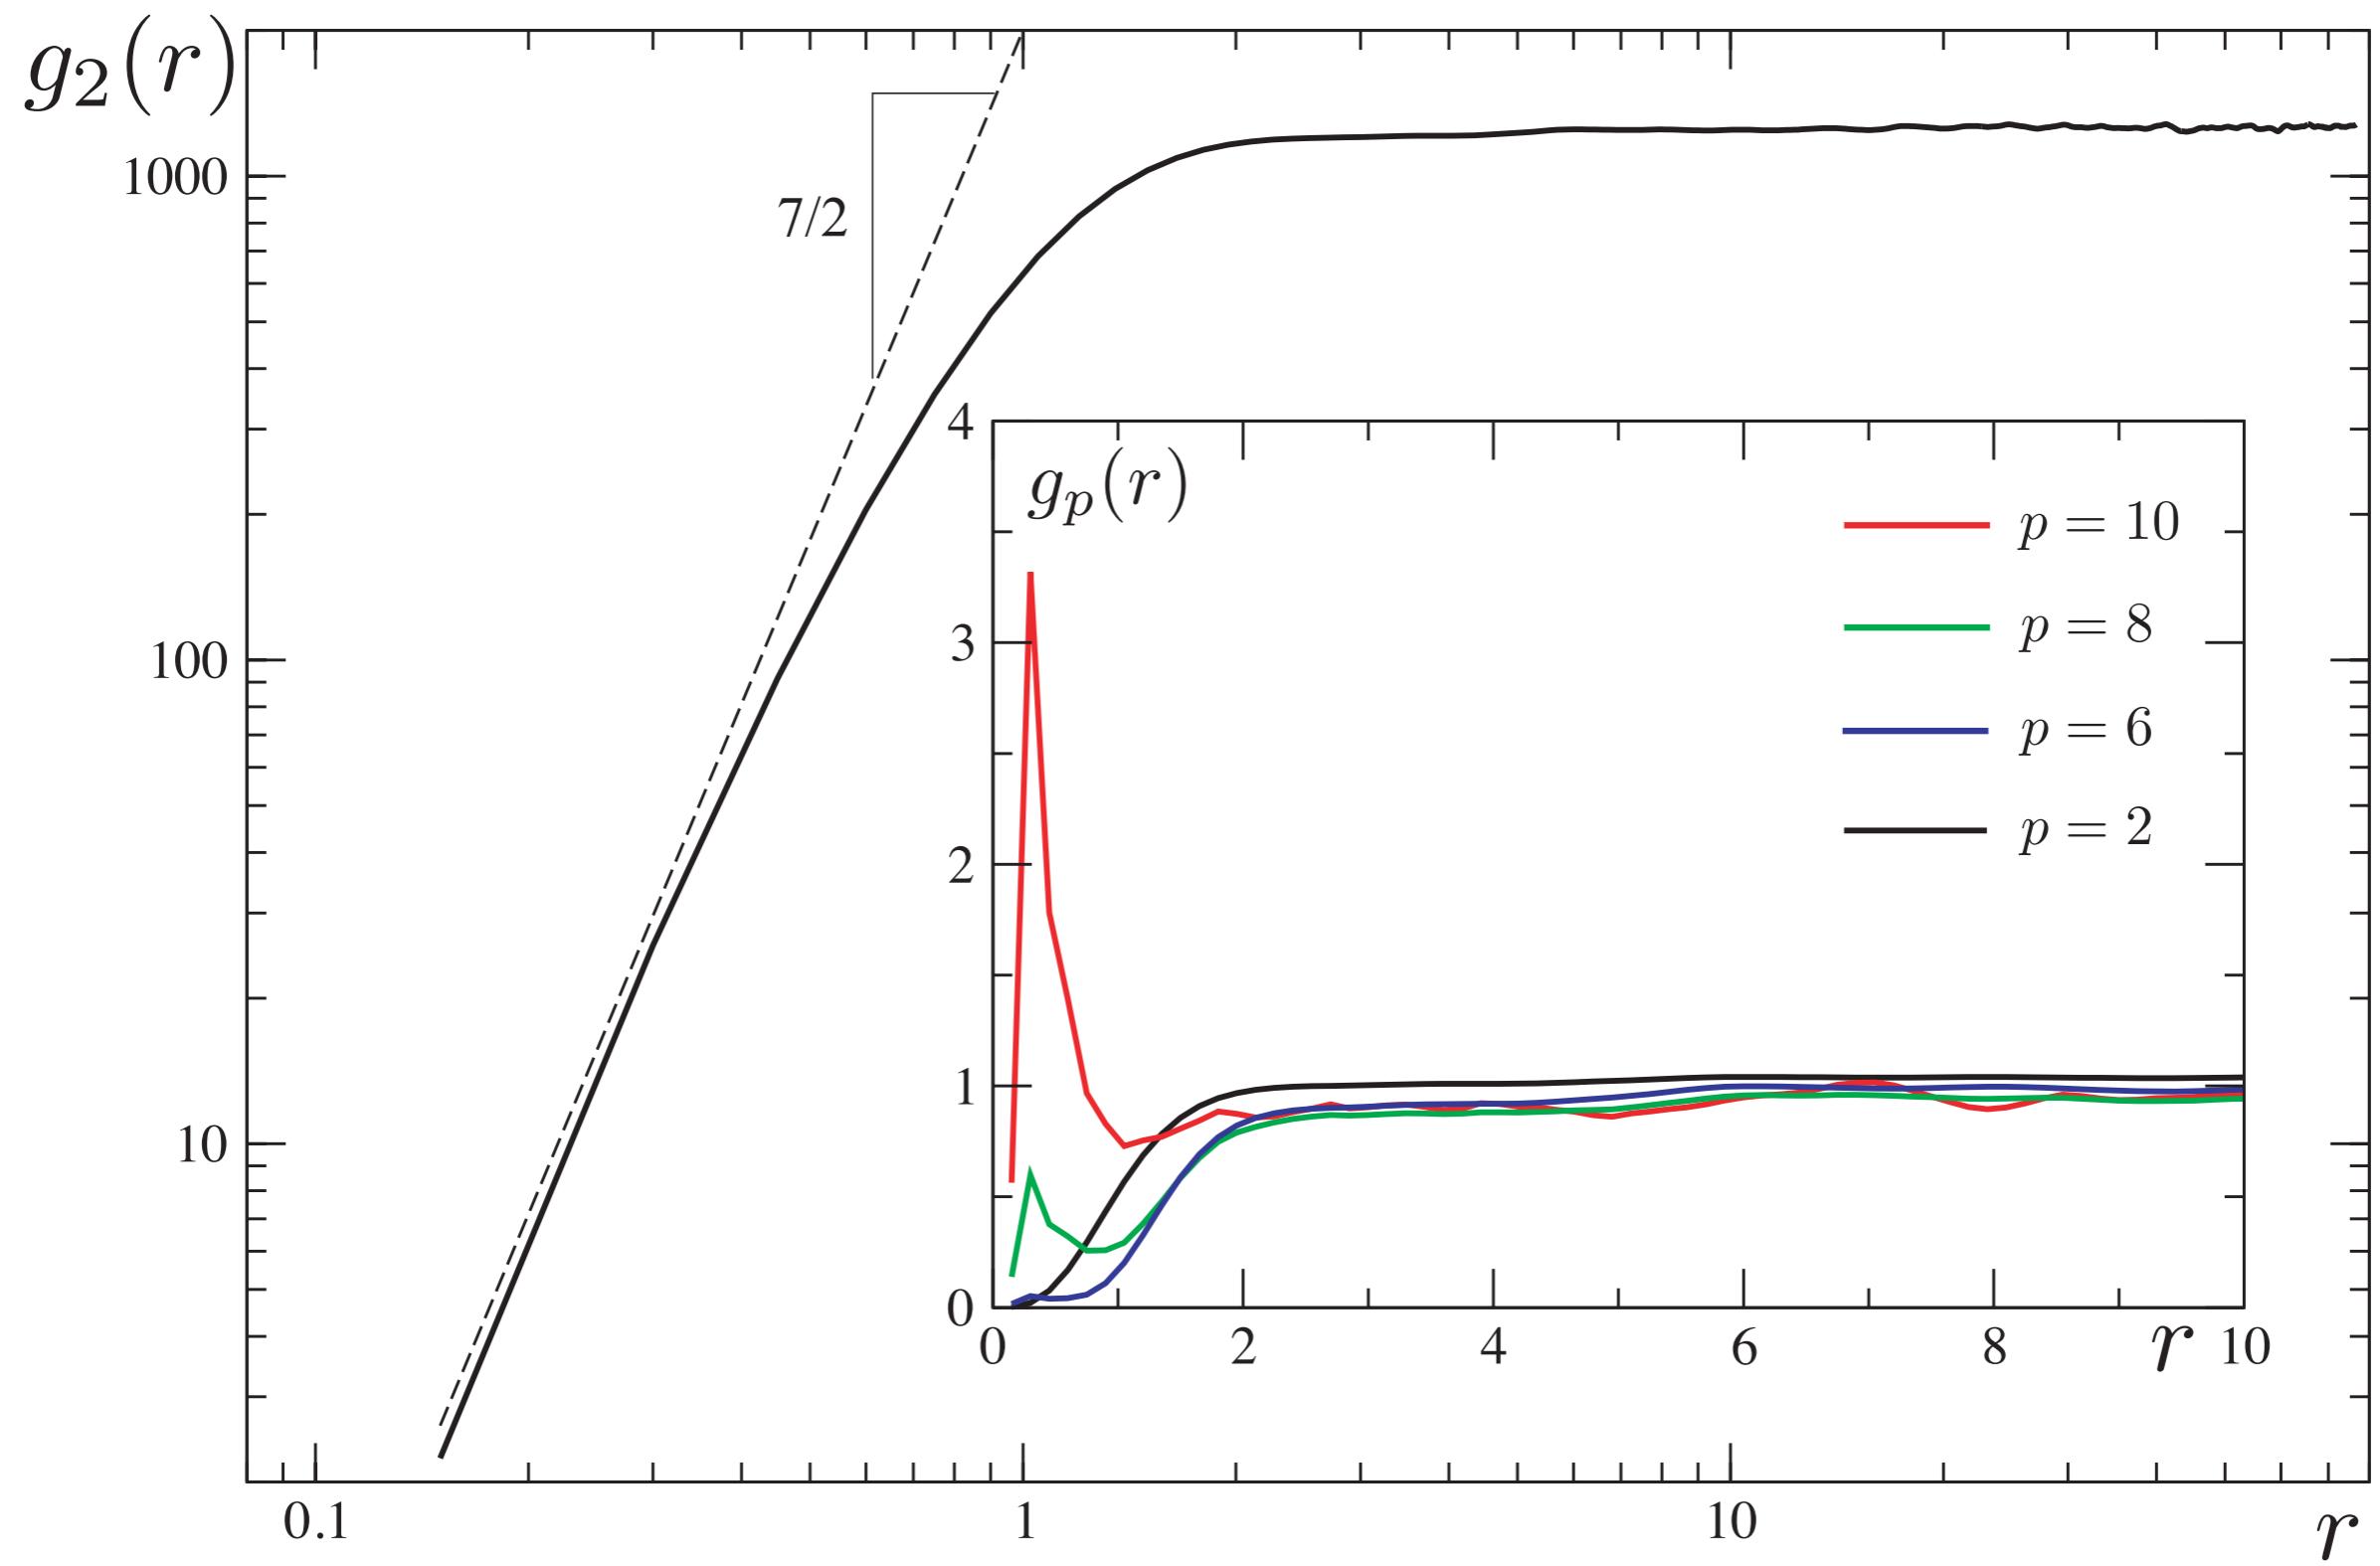

$$g_p(r) = \overline{|\psi(x+r) + \psi(x-r) - 2\psi(x)|^p}$$

p=2 can be deduced from the spectrum scalings

$$g_2(r) \sim r^{7/2} \quad \text{at short scales}$$

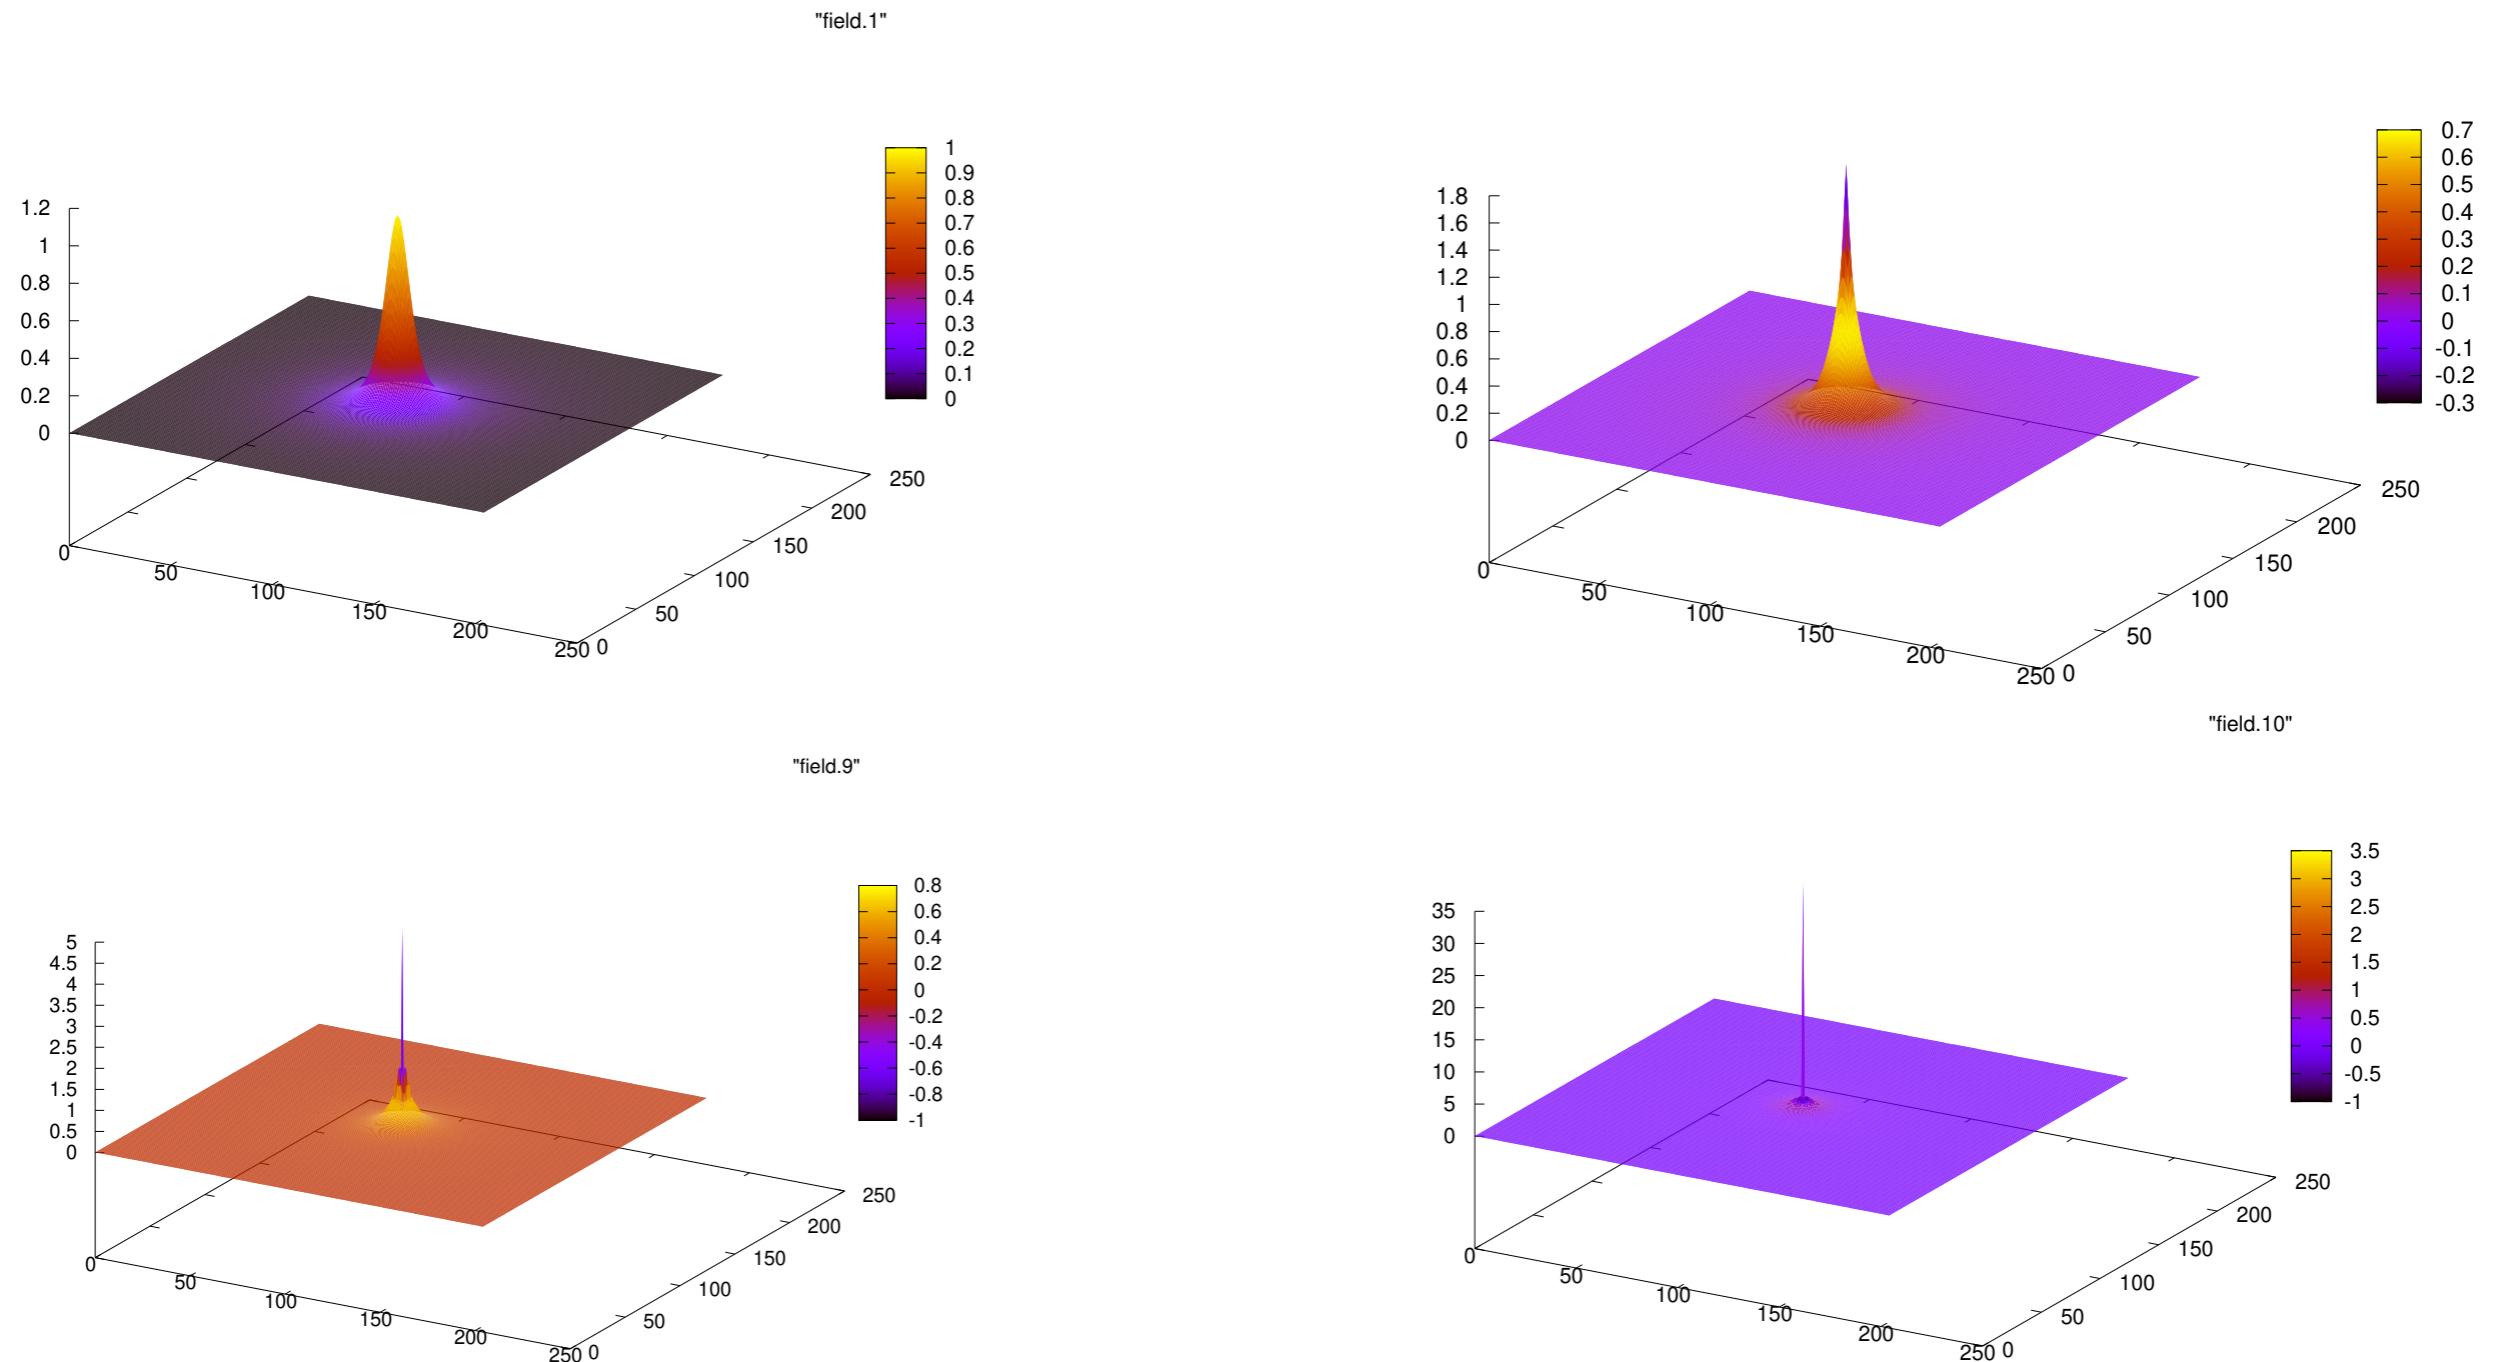

$$g_2(r) \sim r^{-2/3} \quad \text{inertial range}$$

High p's should witness the singularity at small scales

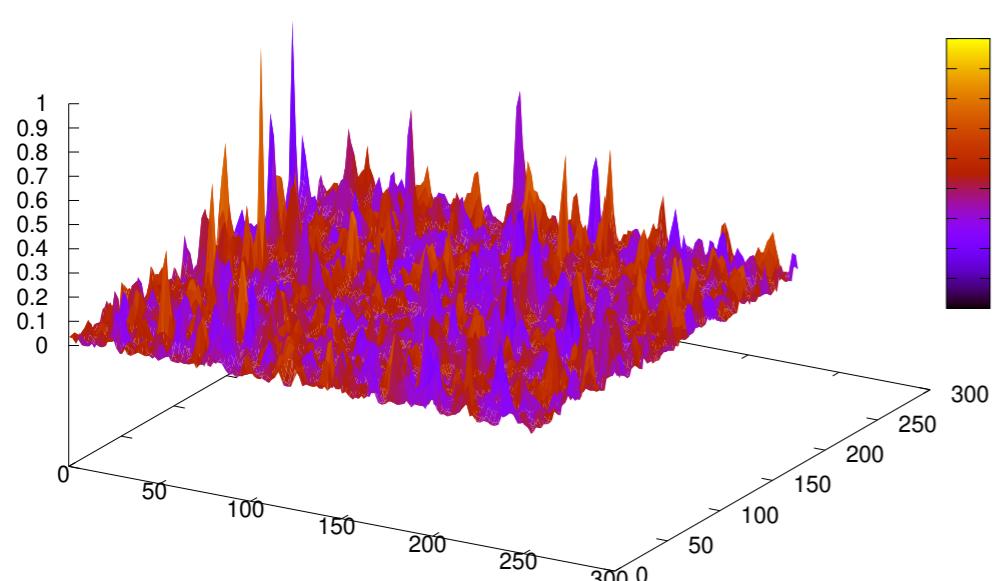

# In higher dimensions?

- Similar investigation in 2D have been done

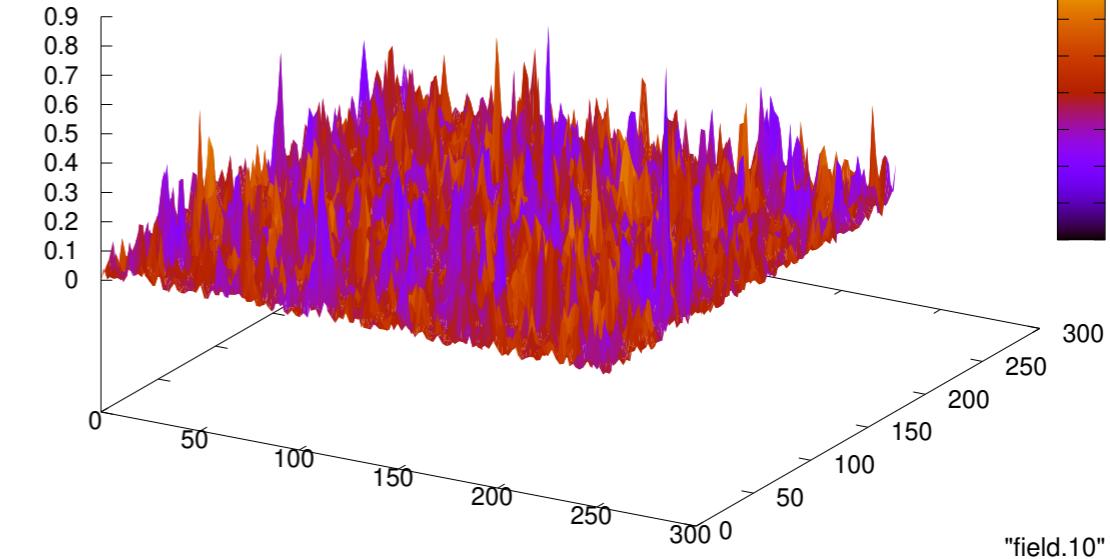

# Turbulent state

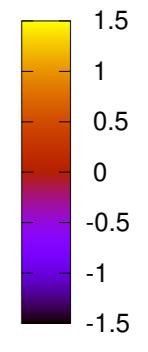

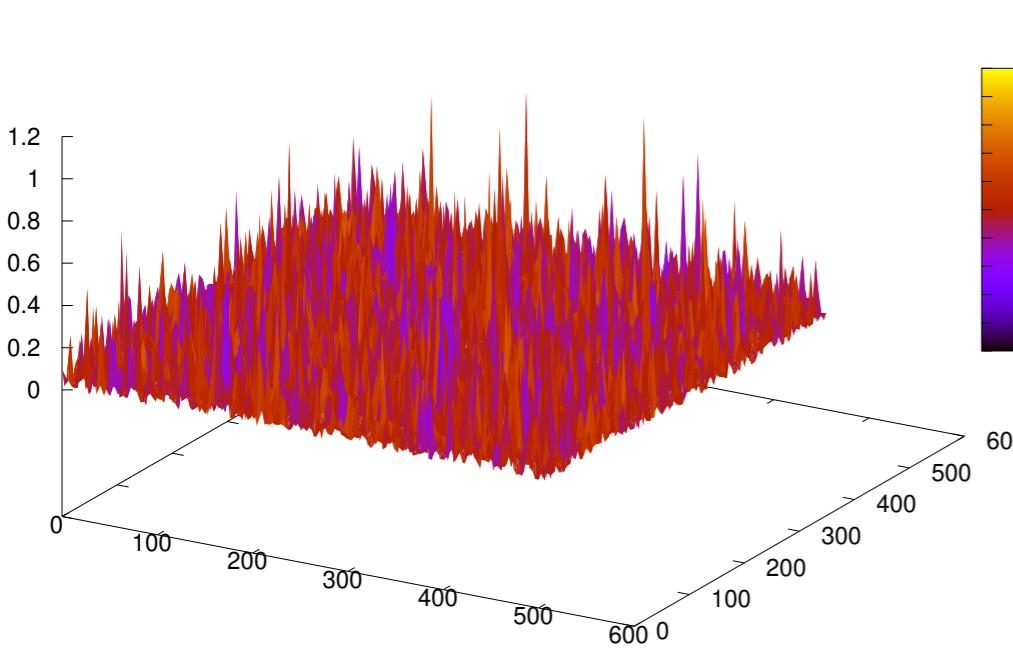

"field.10"

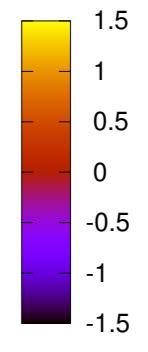

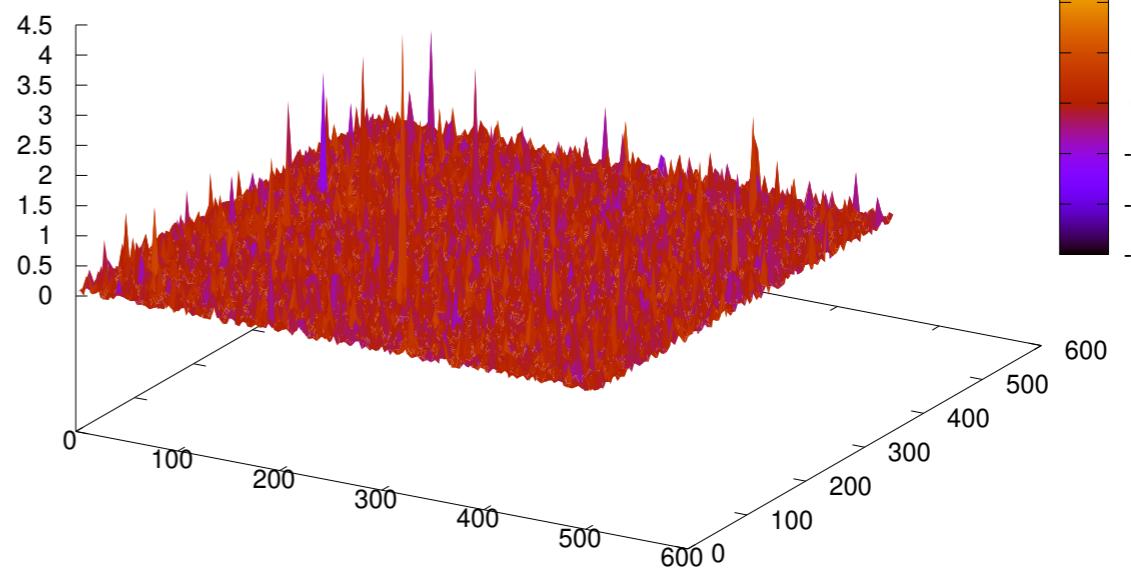

"field.10"

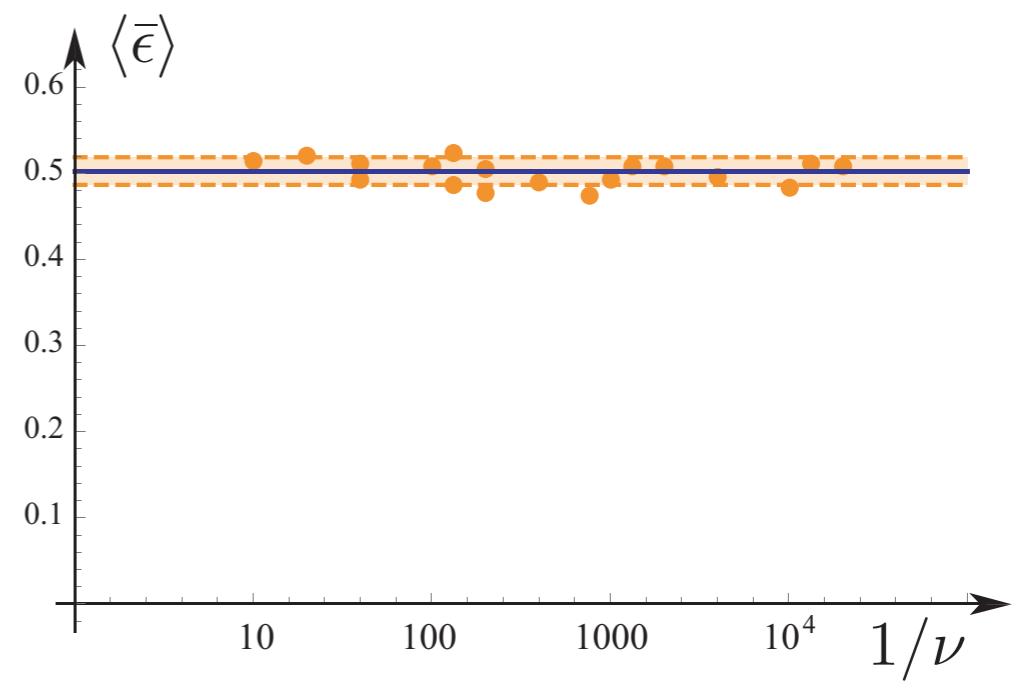

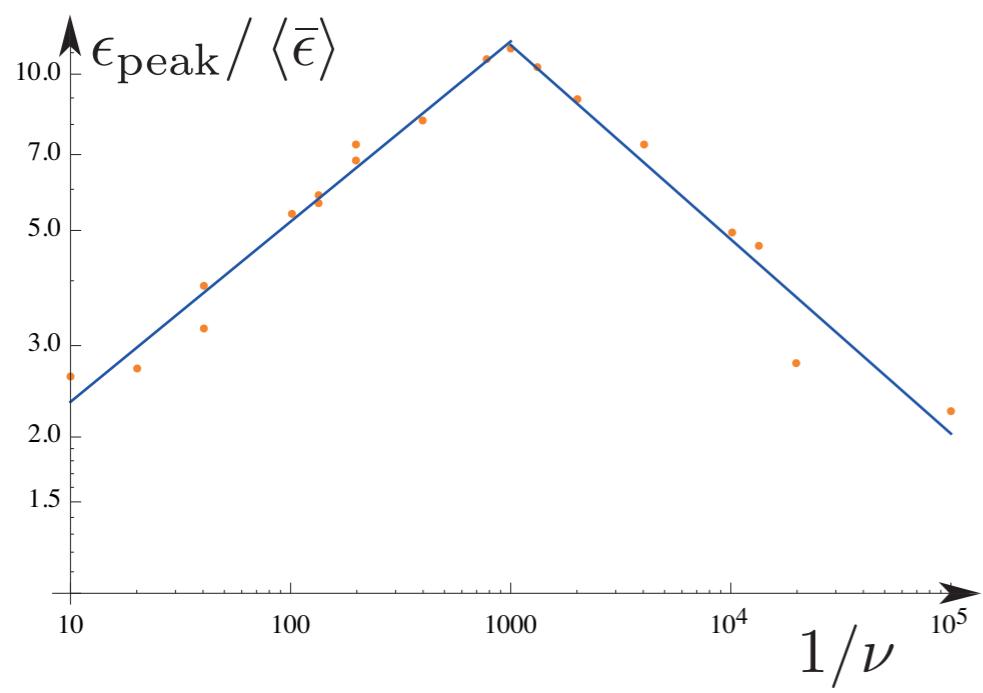

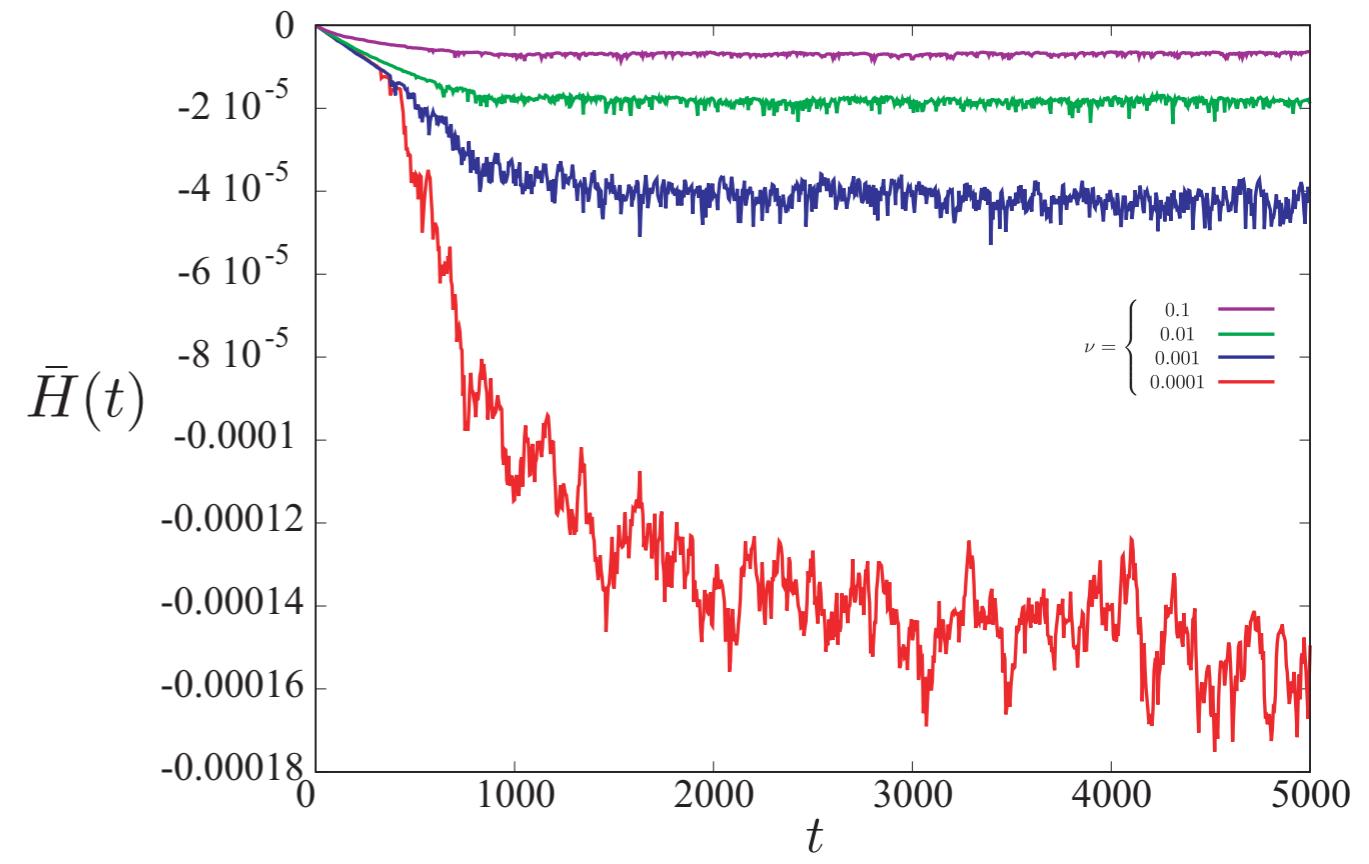

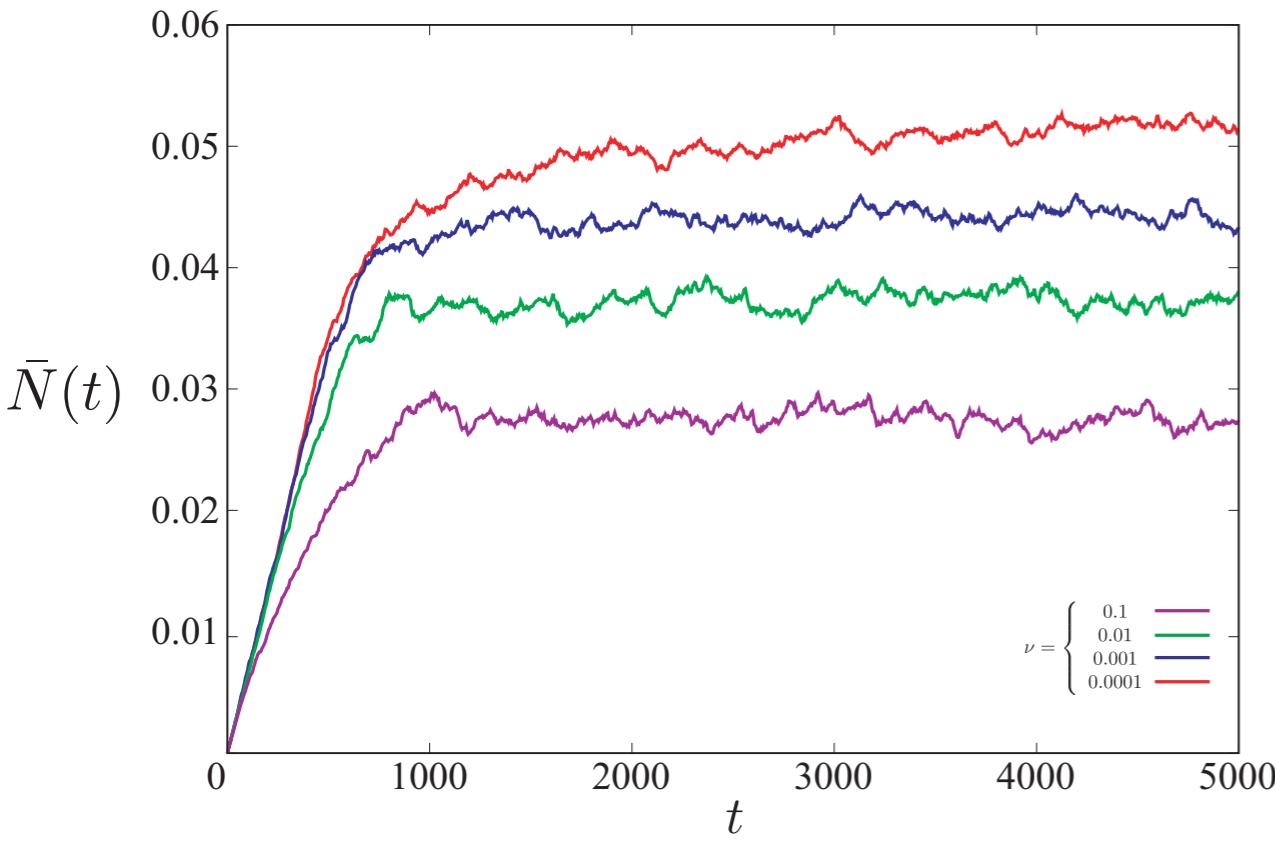

"field.10"

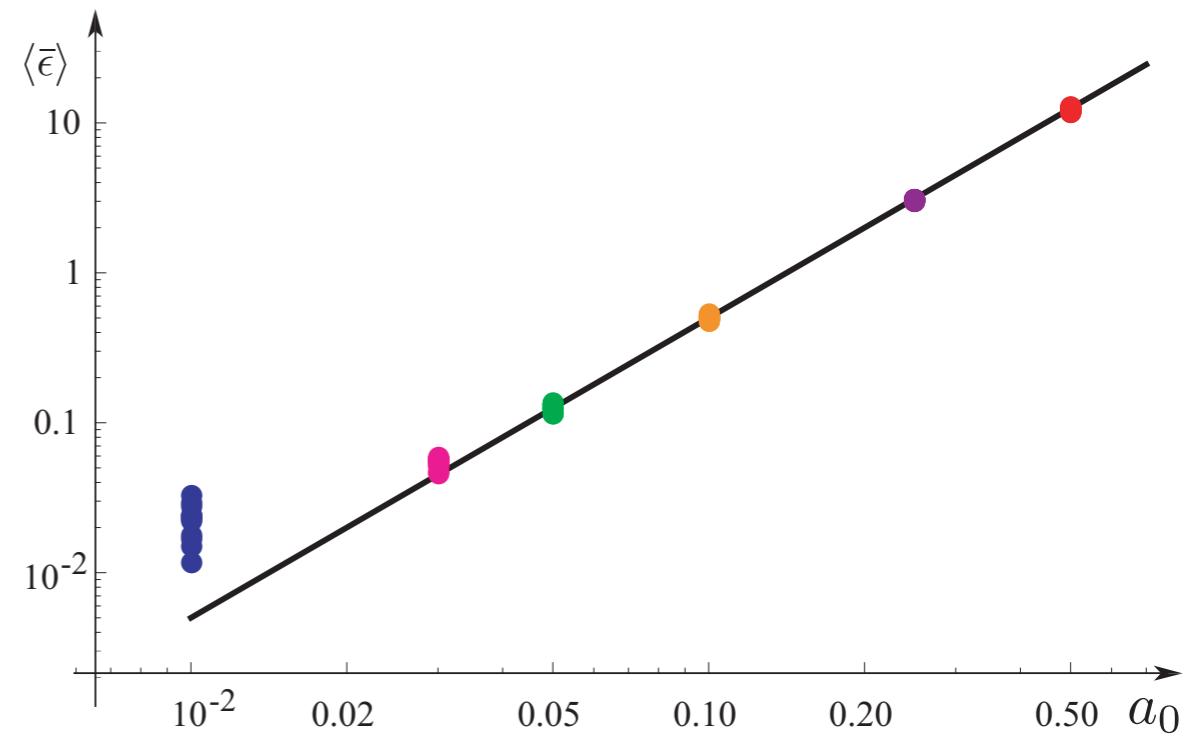

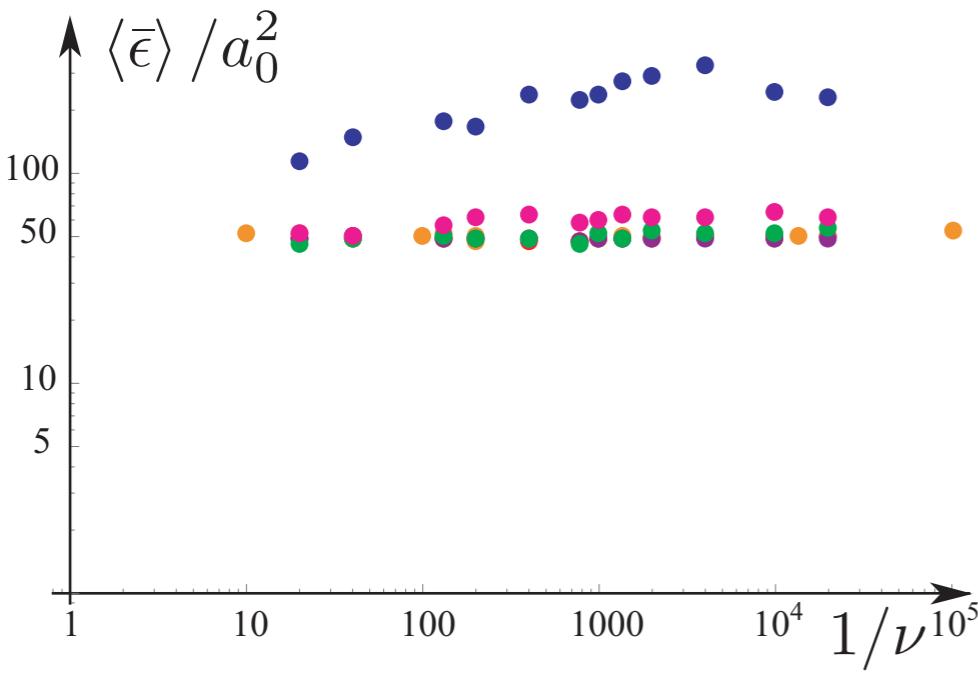

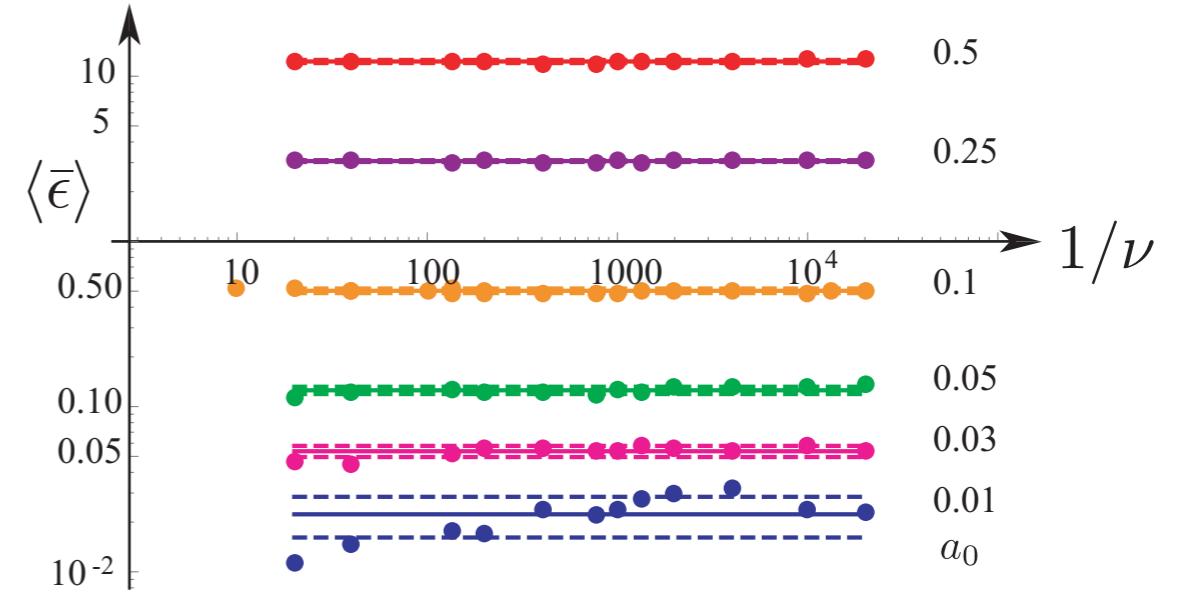

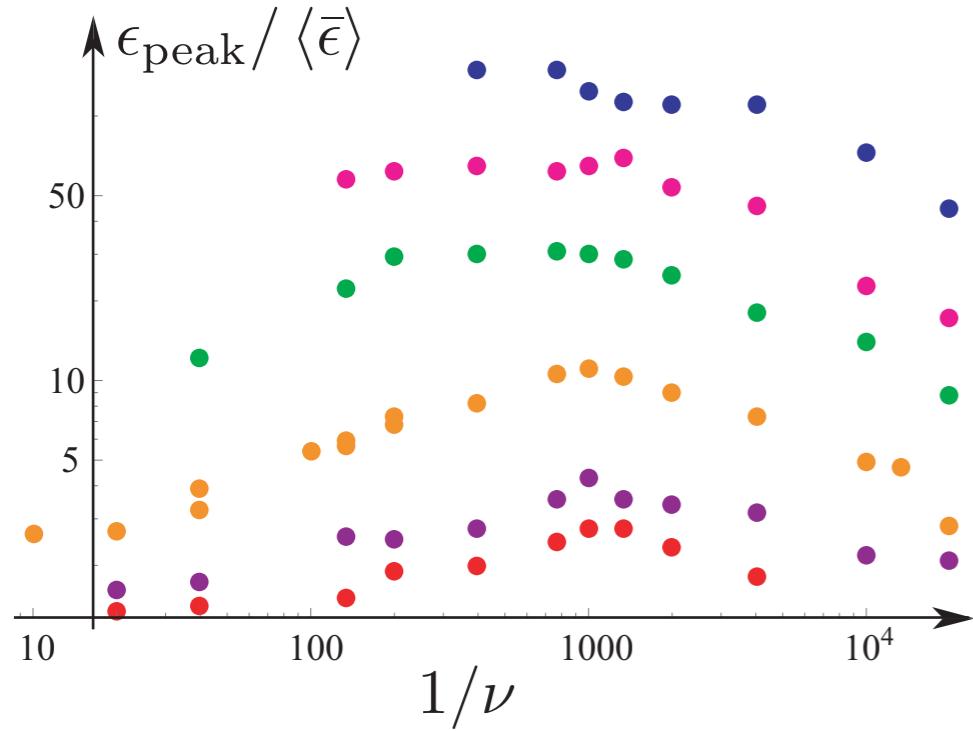

"field.10"

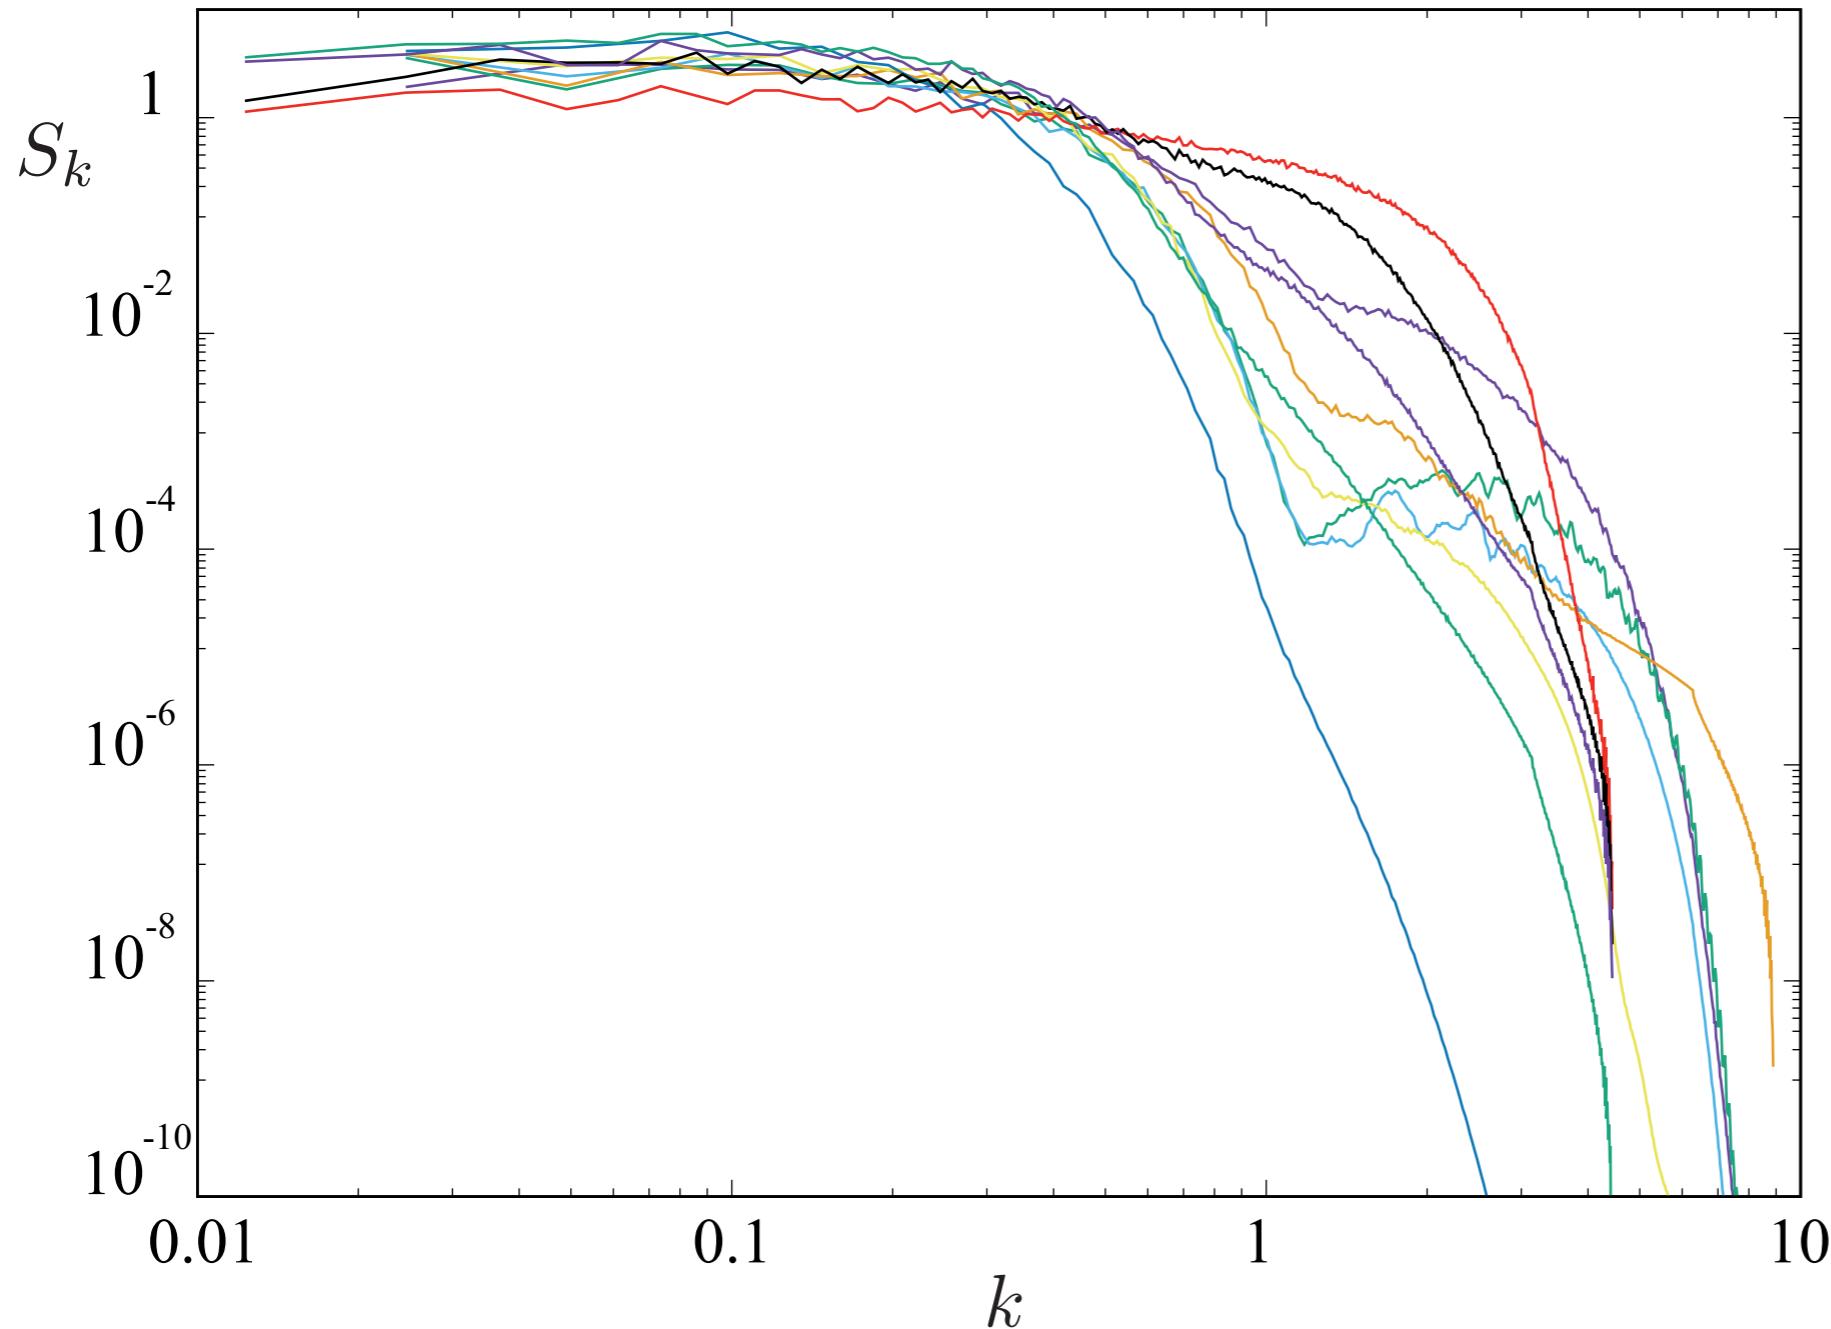

# Influence of the forcing?

# Flat spectrum?

$$S_k = A \frac{\alpha}{\epsilon^{1/3} g^{2/3}}$$

# Conclusion

- « singularity » mediated turbulence (in the spirit of « defect » mediated (Coullet, Gil & Lega 1989) is observed (singularity cured by viscosity) in a version of the focusing NLS
- simple model where singularity in the inviscid limit is known. Mass « cascade »
- dissipation of mass concentrated in the collapses
- Kolmogorov like spectra are observed (needs additional condition for the exponent, different than those of the collapse and of the WTT, possibility of Phillips spectrum)
- singularity manifests through intermittency at high order
